

Package ‘RAINBOWR’

August 18, 2020

Type Package

Title Genome-Wide Association Study with SNP-Set Methods

Version 0.1.21

Maintainer Kosuke Hamazaki <hamazaki@ut-biomet.org>

Description By using 'RAINBOWR' (Reliable Association INference By Optimizing Weights with R), users can test multiple SNPs (Single Nucleotide Polymorphisms) simultaneously by kernel-based (SNP-set) methods. This package can also be applied to haplotype-based GWAS (Genome-Wide Association Study). Users can test not only additive effects but also dominance and epistatic effects. In detail, please check our paper on PLOS Computational Biology: Kosuke Hamazaki and Hiroyoshi Iwata (2020) <doi:10.1371/journal.pcbi.1007663>.

calcGRM

*Function to calculate genomic relationship matrix (GRM)***Description**

Function to calculate genomic relationship matrix (GRM)

Usage

```
calcGRM(
  genoMat,
  methodGRM = "addNOIA",
  kernel.h = "tuned",
  returnWMat = FALSE,
  probaa = NULL,
  probAa = NULL
)
```

Arguments

genoMat	A $N \times M$ matrix of marker genotype
methodGRM	Method to calculate genomic relationship matrix (GRM). We offer the following methods; "addNOIA", "domNOIA", "A.mat", "linear", "gaussian", "exponential", "correlation". For NOIA methods, please refer to Vitezica et al. 2017.
kernel.h	The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
returnWMat	If this argument is TRUE, we will return W matrix instead of GRM. Here, W satisfies $GRM = WW^T$. W corresponds to H matix in Vitezica et al. 2017.
probaa	Probability of being homozygous for the reference allele for each marker. If NULL (default), it will be calculated from genoMat.
probAa	Probability of being heterozygous for the reference and alternative alleles for each marker If NULL (default), it will be calculated from genoMat.

Value

genomic relationship matrix (GRM)

References

- Vitezica, Z.G., Legarra, A., Toro, M.A. and Varona, L. (2017) Orthogonal Estimates of Variances for Additive, Dominance, and Epistatic Effects in Populations. *Genetics*. 206(3): 1297-1307.
- Endelman, J.B. and Jannink, J.L. (2012) Shrinkage Estimation of the Realized Relationship Matrix. *G3 Genes, Genomes, Genet.* 2(11): 1405-1413.

CalcThreshold

Function to calculate threshold for GWAS

Description

Calculate thresholds for the given GWAS (genome-wide association studies) result by the Benjamini-Hochberg method or Bonferroni method.

Usage

```
CalcThreshold(input, sig.level = 0.05, method = "BH")
```

Arguments

input	Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the fourth column is $-\log_{10}(p)$ for each marker.
sig.level	Significance level for the threshold. The default is 0.05. You can also assign vector of significance levels.
method	Two methods are offered: "BH" : Benjamini-Hochberg method. To control FDR, use this method. "Bonf" : Bonferroni method. To perform simple correction of multiple testing, use this method. You can also assign both of them by 'method = c("BH", "Bonf")'

Value

The value of the threshold. If there is no threshold, it returns NA.

References

- Benjamini, Y. and Hochberg, Y. (1995) Controlling the false discovery rate: a practical and powerful approach to multiple testing. *J R Stat Soc.* 57(1): 289-300.

cumsumPos

Function to calculate cumulative position (beyond chromosome)

Description

Function to calculate cumulative position (beyond chromosome)

Usage

```
cumsumPos(map)
```

Arguments

map	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.
-----	---

Value

Cumulative position (beyond chromosome) will be returned.

design.Z	<i>Function to generate design matrix (Z)</i>
----------	---

Description

Function to generate design matrix (Z)

Usage

```
design.Z(pheno.labels, geno.names)
```

Arguments

pheno.labels	A vector of genotype (line; accession; variety) names which correpond to phenotypic values.
geno.names	A vector of genotype (line; accession; variety) names for marker genotype data (duplication is not recommended).

Value

Z of $y = X\beta + Zu + e$. Design matrix, which is useful for GS or GWAS.

EM3.cpp	<i>Equation of mixed model for multi-kernel (slow, general version)</i>
---------	---

Description

This function solves the following multi-kernel linear mixed effects model.

$$y = X\beta + \sum_{l=1}^L Z_l u_l + \epsilon$$

$$\text{where } Var[y] = \sum_{l=1}^L Z_l K_l Z_l' \sigma_l^2 + I \sigma_e^2.$$

Usage

```
EM3.cpp(  
  y,  
  X0 = NULL,  
  ZETA,  
  eigen.G = NULL,  
  eigen.SGS = NULL,  
  tol = NULL,  
  optimizer = "nllminb",  
  traceInside = 0,  
  n.thres = 450,  
  REML = TRUE,  
  pred = TRUE  
)
```

Arguments

<code>y</code>	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
<code>X0</code>	A $n \times p$ matrix. You should assign mean vector (<code>rep(1, n)</code>) and covariates. NA is not allowed.
<code>ZETA</code>	A list of variance matrices and its design matrices of random effects. You can use more than one kernel matrix. For example, <code>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</code> (A for additive, D for dominance) Please set names of lists "Z" and "K"!
<code>eigen.G</code>	A list with \$values Eigen values \$vectors Eigen vectors The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
<code>eigen.SGS</code>	A list with \$values Eigen values \$vectors Eigen vectors The result of the eigen decomposition of SGS , where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
<code>tol</code>	The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.
<code>optimizer</code>	The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
<code>traceInside</code>	Perform trace for the optimization if <code>traceInside</code> ≥ 1 , and this argument shows the frequency of reports.
<code>n.thres</code>	If $n \geq n.thres$, perform EMM1.cpp. Else perform EMM2.cpp.
<code>REML</code>	You can choose which method you will use, "REML" or "ML". If <code>REML</code> = TRUE, you will perform "REML", and if <code>REML</code> = FALSE, you will perform "ML".
<code>pred</code>	If TRUE, the fitting values of <code>y</code> is returned.

Value

\$y.pred	The fitting values of $y = X\beta + Zu$
\$Vu	Estimator for σ_u^2 , all of the genetic variance
\$Ve	Estimator for σ_e^2
\$beta	BLUE(β)
\$u	BLUP(u)
\$weights	The proportion of each genetic variance (corresponding to each kernel of ZETA) to Vu
\$LL	Maximized log-likelihood (full or restricted, depending on method)
\$Vinv	The inverse of $V = Vu \times ZKZ' + Ve \times I$
\$Hinv	The inverse of $H = ZKZ' + \lambda I$

```

EM3.linker.cpp

Equation of mixed model for multi-kernel (fast, for limited cases)

Description

This function solves multi-kernel mixed model using fastlmm.snpset approach (Lippert et al., 2014). This function can be used only when the kernels other than genomic relationship matrix are linear

kernels.

Usage

```
EM3.linker.cpp(
  y0,
  X0 = NULL,
  ZETA = NULL,
  Zs0 = NULL,
  Ws0,
  Gammas0 = lapply(Ws0, function(x) diag(ncol(x))),
  gammas.diag = TRUE,
  X.fix = TRUE,
  eigen.SGS = NULL,
  eigen.G = NULL,
  tol = NULL,
  bounds = c(1e-06, 1e+06),
  optimizer = "nllminb",
  traceInside = 0,
  n.thres = 450,
  spectral.method = NULL,
  REML = TRUE,
  pred = TRUE
)
```

Arguments

<code>y0</code>	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
<code>X0</code>	A $n \times p$ matrix. You should assign mean vector (<code>rep(1, n)</code>) and covariates. NA is not allowed.
<code>ZETA</code>	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, <code>ZETA = list(A = list(Z = Z, K = K))</code> Please set names of list "Z" and "K"!
<code>Zs0</code>	A list of design matrices (Z ; $n \times m$ matrix) for W_s . For example, <code>Zs0 = list(A.part = Z.A.part, D.part = Z.D.part)</code>
<code>Ws0</code>	A list of low rank matrices (W ; $m \times k$ matrix). This forms linear kernel $K = WTW'$. For example, <code>Ws0 = list(A.part = W.A, D.part = W.D)</code>
<code>Gammas0</code>	A list of matrices for weighting SNPs (Gamma; $k \times k$ matrix). This forms linear kernel $K = WTW'$. For example, if there is no weighting, <code>Gammas0 = lapply(Ws0, function(x) diag(ncol(x)))</code>
<code>gammas.diag</code>	If each Gamma is the diagonal matrix, please set this argument TRUE. The calculation time can be saved.
<code>X.fix</code>	If you repeat this function and when <code>X0</code> is fixed during iterations, please set this argument TRUE.
<code>eigen.SGS</code>	A list with \$values Eigen values \$vectors Eigen vectors The result of the eigen decomposition of SGS , where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function.

	We recommend you assign the result of the eigen decomposition beforehand for time saving.
eigen.G	A list with \$values Eigen values \$vectors Eigen vectors The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
tol	The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.
bounds	Lower and upper bounds for weights.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlnmb" functions.
traceInside	Perform trace for the optimization if traceInside ≥ 1 , and this argument shows the frequency of reports.
n.thres	If $n \geq n.thres$, perform EMM1.cpp. Else perform EMM2.cpp.
spectral.method	The method of spectral decomposition. In this function, "eigen" : eigen decomposition and "cholesky" : cholesky and singular value decomposition are offered. If this argument is NULL, either method will be chosen according to the dimension of Z and X.
REML	You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".
pred	If TRUE, the fitting values of y is returned.

Value

\$y.pred	The fitting values of y $y = X\beta + Zu$
\$Vu	Estimator for σ_u^2 , all of the genetic variance
\$Ve	Estimator for σ_e^2
\$beta	BLUE(β)
\$u	BLUP(u)
\$weights	The proportion of each genetic variance (corresponding to each kernel of ZETA) to Vu
\$LL	Maximized log-likelihood (full or restricted, depending on method)
\$Vinv	The inverse of $V = Vu \times ZKZ' + Ve \times I$
\$Hinv	The inverse of $H = ZKZ' + \lambda I$

EMM.cpp

*Equation of mixed model for one kernel, a wrapper of two methods***Description**

This function estimates maximum-likelihood (ML/REML; restricted maximum likelihood) solutions for the following mixed model.

$$y = X\beta + Zu + \epsilon$$

where β is a vector of fixed effects and u is a vector of random effects with $Var[u] = K\sigma_u^2$. The residual variance is $Var[\epsilon] = I\sigma_e^2$.

Usage

```
EMM.cpp(
  y,
  X = NULL,
  ZETA,
  eigen.G = NULL,
  eigen.SGS = NULL,
  n.thres = 450,
  reestimation = FALSE,
  lam.len = 4,
  init.range = c(1e-06, 100),
  init.one = 0.5,
  conv.param = 1e-06,
  count.max = 20,
  bounds = c(1e-06, 1e+06),
  tol = NULL,
  optimizer = "nllminb",
  traceInside = 0,
  REML = TRUE,
  silent = TRUE,
  plot.l = FALSE,
  SE = FALSE,
  return.Hinv = TRUE
)
```

Arguments

y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.

ZETA	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, <code>ZETA = list(A = list(Z = Z, K = K))</code> Please set names of list "Z" and "K"!
eigen.G	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
eigen.SGS	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of SGS, where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
n.thres	If $n \geq n.thres$, perform EMM1.cpp. Else perform EMM2.cpp.
reestimation	If TRUE, EMM2.cpp is performed when the estimation by EMM1.cpp may not be accurate.
lam.len	The number of initial values you set. If this number is large, the estimation will be more accurate, but computational cost will be large. We recommend setting this value $3 \leq lam.len \leq 6$.
init.range	The range of the initial parameters. For example, if <code>lam.len = 5</code> and <code>init.range = c(1e-06, 1e02)</code> , corresponding initial heritabilities will be calculated as <code>seq(1e-06, 1 - 1e-02, length = 5)</code> , and then initial lambdas will be set.
init.one	The initial parameter if <code>lam.len = 1</code> .
conv.param	The convergence parameter. If the difference of log-likelihood by updating the parameter "lambda" is smaller than this <code>conv.param</code> , the iteration steps will be stopped.
count.max	Sometimes algorithms won't converge for some initial parameters. So if the iteration steps reach to this argument, you can stop the calculation even if algorithm doesn't converge.
bounds	Lower and Upper bounds of the parameter lambda. If the updated parameter goes out of this range, the parameter is reset to the value in this range.
tol	The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
traceInside	Perform trace for the optimization if <code>traceInside >= 1</code> , and this argument shows the frequency of reports.
REML	You can choose which method you will use, "REML" or "ML". If <code>REML = TRUE</code> , you will perform "REML", and if <code>REML = FALSE</code> , you will perform "ML".

<code>silent</code>	If this argument is TRUE, warning messages will be shown when estimation is not accurate.
<code>plot.l</code>	If you want to plot log-likelihood, please set <code>plot.l = TRUE</code> . We don't recommend <code>plot.l = TRUE</code> when <code>lam.len >= 2</code> .
<code>SE</code>	If TRUE, standard errors are calculated.
<code>return.Hinv</code>	If TRUE, the function returns the inverse of $H = ZKZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$. This is useful for GWAS.

Value

\$Vu Estimator for σ_u^2
\$Ve Estimator for σ_e^2
\$beta BLUE(β)
\$u BLUP(u)
\$LL Maximized log-likelihood (full or restricted, depending on method)
\$beta.SE Standard error for β (If SE = TRUE)
\$u.SE Standard error for $u^* - u$ (If SE = TRUE)
\$Hinv The inverse of $H = ZKZ' + \lambda I$ (If return.Hinv = TRUE)
\$Hinv2 The inverse of $H2 = ZKZ' / \lambda + I$ (If return.Hinv = TRUE)
\$lambda Estimators for $\lambda = \sigma_e^2 / \sigma_u^2$ (If $n \geq n.thres$)
\$lambdas Lambdas for each initial values (If $n \geq n.thres$)
\$reest If parameter estimation may not be accurate, reest = 1, else reest = 0 (If $n \geq n.thres$)
\$counts The number of iterations until convergence for each initial values (If $n \geq n.thres$)

```

EMM1.cpp

Equation of mixed model for one kernel, GEMMA-based method (implemented by Rcpp)

Description

This function solves the single-kernel linear mixed effects model by GEMMA (genome wide efficient mixed model association; Zhou et al., 2012) approach.

Usage

```

EMM1.cpp(
  y,
  X = NULL,
  ZETA,
  eigen.G = NULL,
  lam.len = 4,
  init.range = c(1e-04, 100),
  init.one = 0.5,
  conv.param = 1e-06,
  count.max = 15,
  bounds = c(1e-06, 1e+06),
  tol = NULL,
  REML = TRUE,
  silent = TRUE,
  plot.l = FALSE,
  SE = FALSE,
  return.Hinv = TRUE
)

```

Arguments

- | | |
|---------|--|
| y | A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed. |
| X | A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed. |
| ZETA | A list of variance (relationship) matrix (K; $m \times m$) and its design matrix (Z; $n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"! |
| eigen.G | A list with
\$values Eigen values |

\$vectors Eigen vectors

The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

lam.len	The number of initial values you set. If this number is large, the estimation will be more accurate, but computational cost will be large. We recommend setting this value $3 \leq \text{lam.len} \leq 6$.
init.range	The range of the initial parameters. For example, if lam.len = 5 and init.range = c(1e-06, 1e02), corresponding initial heritabilities will be calculated as seq(1e-06, 1 - 1e-02, length = 5), and then initial lambdas will be set.
init.one	The initial parameter if lam.len = 1.
conv.param	The convergence parameter. If the difference of log-likelihood by updating the parameter "lambda" is smaller than this conv.param, the iteration steps will be stopped.
count.max	Sometimes algorithms won't converge for some initial parameters. So if the iteration steps reach to this argument, you can stop the calculation even if algorithm doesn't converge.
bounds	Lower and Upper bounds of the parameter $1 / \text{lambda}$. If the updated parameter goes out of this range, the parameter is reset to the value in this range.
tol	The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.
REML	You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".
silent	If this argument is TRUE, warning messages will be shown when estimation is not accurate.
plot.l	If you want to plot log-likelihood, please set plot.l = TRUE. We don't recommend plot.l = TRUE when lam.len ≥ 2 .
SE	If TRUE, standard errors are calculated.
return.Hinv	If TRUE, the function returns the inverse of $H = ZKZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$. This is useful for GWAS.

Value

\$Vu Estimator for σ_u^2

\$Ve Estimator for σ_e^2

\$beta BLUE(β)

\$u BLUP(u)

\$LL Maximized log-likelihood (full or restricted, depending on method)

\$beta.SE Standard error for β (If SE = TRUE)

\$u.SE Standard error for $u^* - u$ (If SE = TRUE)

\$Hinv The inverse of $H = ZKZ' + \lambda I$ (If return.Hinv = TRUE)

\$Hinv2 The inverse of $H2 = ZKZ' / \lambda + I$ (If return.Hinv = TRUE)

\$lambda Estimators for $\lambda = \sigma_e^2 / \sigma_u^2$

\$lambdas Lambdas for each initial values

\$reest If parameter estimation may not be accurate, reest = 1, else reest = 0

\$counts The number of iterations until convergence for each initial values

EMM2.cpp

Equation of mixed model for one kernel, EMMA-based method (implemented by Rcpp)

Description

This function solves single-kernel linear mixed model by EMMA (efficient mixed model association; Kang et al., 2008) approach.

Usage

```
EMM2.cpp(
  y,
  X = NULL,
  ZETA,
  eigen.G = NULL,
  eigen.SGS = NULL,
  tol = NULL,
  optimizer = "nlminb",
  traceInside = 0,
  REML = TRUE,
  bounds = c(1e-09, 1e+09),
  SE = FALSE,
  return.Hinv = FALSE
)
```

Arguments

y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA	A list of variance (relationship) matrix (K; $m \times m$) and its design matrix (Z; $n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
eigen.G	A list with \$values Eigen values \$vectors Eigen vectors

	<p>The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
eigen.SGS	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of SGS, where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
tol	<p>The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.</p>
optimizer	<p>The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.</p>
traceInside	<p>Perform trace for the optimization if traceInside ≥ 1, and this argument shows the frequency of reports.</p>
REML	<p>You can choose which method you will use, "REML" or "ML". If REML = TRUE, you will perform "REML", and if REML = FALSE, you will perform "ML".</p>
bounds	<p>Lower and Upper bounds of the parameter lambda. If the updated parameter goes out of this range, the parameter is reset to the value in this range.</p>
SE	<p>If TRUE, standard errors are calculated.</p>
return.Hinv	<p>If TRUE, the function returns the inverse of $H = ZKZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$. This is useful for GWAS.</p>

Value

\$Vu	Estimator for σ_u^2
\$Ve	Estimator for σ_e^2
\$beta	BLUE(β)
\$u	BLUP(u)
\$LL	Maximized log-likelihood (full or restricted, depending on method)
\$beta.SE	Standard error for β (If SE = TRUE)
\$u.SE	Standard error for $u^* - u$ (If SE = TRUE)
\$Hinv	The inverse of $H = ZKZ' + \lambda I$ (If return.Hinv = TRUE)

  colCompBase = c(2, 4),
```

```

colHaploBase = c(3, 5, 6),
cexMax = 2,
cexMin = 0.7,
ggPlotNetwork = FALSE,
cexMaxForGG = 0.2,
cexMinForGG = 0.1,
alphaBase = c(0.9, 0.3),
verbose = TRUE
)

```

Arguments

blockInterest	A $n \times M$ matrix representing the marker genotype that belongs to the haplotype block of interest. If this argument is NULL, this argument will automatically be determined by 'geno'.
gwasRes	You can use the results (data.frame) of haplotype-based (SNP-set) GWAS by 'RGWAS.multisnp' function.
nTopRes	Haplotype blocks (or gene sets, SNP-sets) with top 'nTopRes' p-values by 'gwas-Res' will be used.
gene.set	If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
indexRegion	You can specify the haplotype block (or gene set, SNP-set) of interest by the marker index in 'geno'.
chrInterest	You can specify the haplotype block (or gene set, SNP-set) of interest by the marker position in 'geno'. Please assign the chromosome number to this argument.
posRegion	You can specify the haplotype block (or gene set, SNP-set) of interest by the marker position in 'geno'. Please assign the position in the chromosome to this argument.
blockName	You can specify the haplotype block (or gene set, SNP-set) of interest by the name of haplotype block in 'geno'.
pheno	Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
geno	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.
ZETA	<p>A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,</p> <p><code>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</code></p> <p>Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.</p> <p>K.A, K.D Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.</p>

chi2Test	If TRUE, chi-square test for the relationship between haplotypes & subpopulations will be performed.
thresChi2Test	The threshold for the chi-square test.
plotNetwork	If TRUE, the function will return the plot of haplotype network.
distMat	You can assign the distance matrix of the block of interest. If NULL, the distance matrix will be computed in this function.
distMethod	You can choose the method to calculate distance between accessions. This argument corresponds to the 'method' argument in the 'dist' function.
evolutionDist	If TRUE, the evolution distance will be used instead of the pure distance. The 'distMat' will be converted to the distance matrix by the evolution distance when you use 'complementHaplo = "phylo"'. complementHaplo
	how to complement unobserved haplotypes. When 'complementHaplo = "all"', all possible haplotypes will be complemented from the observed haplotypes. When 'complementHaplo = "never"', unobserved haplotypes will not be complemented. When 'complementHaplo = "phylo"', unobserved haplotypes will be complemented as nodes of phylogenetic tree. When 'complementHaplo = "TCS"', unobserved haplotypes will be complemented by TCS methods (Clement et al., 2002).
subpopInfo	The information of subpopulations. This argument should be a vector of factor.
groupingMethod	If 'subpopInfo' argument is NULL, this function estimates subpopulation information from marker genotype. You can choose the grouping method from 'kmeans', 'kmedoids', and 'hclust'.
nGrp	The number of groups (or subpopulations) grouped by 'groupingMethod'. If this argument is 0, the subpopulation information will not be estimated.
nIterClustering	If 'groupingMethod' = 'kmeans', the clustering will be performed multiple times. This argument specifies the number of classification performed by the function.
iterRmst	The number of iterations for RMST (randomized minimum spanning tree).
networkMethod	Either one of 'mst' (minimum spanning tree), 'msn' (minimum spanning network), and 'rmst' (randomized minimum spanning tree). 'rmst' is recommended.
autogamous	This argument will be valid only when you use 'complementHaplo = "all"' or 'complementHaplo = "TCS"'. This argument specifies whether the plant is autogamous or not. If autogamous = TRUE, complemented haplotype will consist of only homozygous sites (-1, 1). If FALSE, complemented haplotype will consist of both homozygous & heterozygous sites (-1, 0, 1).
probParsimony	Equal to the argument 'prob' in 'haplotypes::parsimnet' function: A numeric vector of length one in the range [0.01, 0.99] giving the probability of parsimony as defined in Templeton et al. (1992). In order to set maximum connection steps to Inf (to connect all the haplotypes in a single network), set the probability to NULL.
nMaxHaplo	The maximum number of haplotypes. If the number of total (complemented + original) haplotypes are larger than 'nMaxHaplo', we will only show the results only for the original haplotypes to reduce the computational time.
kernelTypes	In the function, similarity matrix between accessions will be computed from marker genotype to estimate genotypic values. This argument specifies the method to compute similarity matrix: If this argument is 'addNOIA' (or one

	of other options in 'methodGRM' in 'calcGRM'), then the 'addNOIA' (or corresponding) option in the 'calcGRM' function will be used, and if this argument is 'diffusion', the diffusion kernel based on Laplacian matrix will be computed from network. You can assign more than one kernelTypes for this argument; for example, kernelTypes = c("addNOIA", "diffusion").
nCores	The number of cores used for optimization.
hOpt	Optimized hyper parameter for constructing kernel when estimating haplotype effects. If hOpt = "optimized", hyper parameter will be optimized in the function. If hOpt is numeric, that value will be directly used in the function.
hOpt2	Optimized hyper parameter for constructing kernel when estimating complemented haplotype effects. If hOpt2 = "optimized", hyper parameter will be optimized in the function. If hOpt2 is numeric, that value will be directly used in the function.
maxIter	Max number of iterations for optimization algorithm.
rangeHStart	The median of off-diagonal of distance matrix multiplied by rangeHStart will be used as the initial values for optimization of hyper parameters.
saveName	When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.
saveStyle	This argument specifies how to save the plot of phylogenetic tree. The function offers 'png', 'pdf', 'jpg', and 'tiff'.
plotWhichMDS	We will show the MDS (multi-dimensional scaling) plot, and this argument is a vector of two integers specifying that will define which MDS dimension will be plotted. The first and second integers correspond to the horizontal and vertical axes, respectively.
colConnection	A vector of two integers or characters specifying the colors of connection between nodes for the original and complemented haplotypes, respectively.
ltyConnection	A vector of two characters specifying the line types of connection between nodes for the original and complemented haplotypes, respectively.
lwdConnection	A vector of two integers specifying the line widths of connection between nodes for the original and complemented haplotypes, respectively.
pchBase	A vector of two integers specifying the plot types for the positive and negative genotypic values respectively.
colCompBase	A vector of two integers or characters specifying color of complemented haplotypes for the positive and negative genotypic values respectively.
colHaploBase	A vector of integers or characters specifying color of original haplotypes for the positive and negative genotypic values respectively. The length of the vector should equal to the number of subpopulations.
cexMax	A numeric specifying the maximum point size of the plot.
cexMin	A numeric specifying the minimum point size of the plot.
ggPlotNetwork	If TRUE, the function will return the ggplot version of haplotype network. It offers the precise information on subgroups for each haplotype.
cexMaxForGG	A numeric specifying the maximum point size of the plot for the ggplot version of haplotype network, relative to the range of x and y-axes ($0 < \text{cexMaxForGG} \leq 1$).
cexMinForGG	A numeric specifying the minimum point size of the plot for the ggplot version of haplotype network, relative to the range of x and y-axes ($0 < \text{cexMaxForGG} \leq 1$).

alphaBase	alpha (parameter that indicates the opacity of a geom) for original haplotype with positive / negative effects. alpha for complemented haplotype will be same as the alpha for original haplotype with negative effects.
verbose	If this argument is TRUE, messages for the current steps will be shown.

Value

A list / lists of

A list of haplotype information with

\$haploTypeID A vector indicating each individual belongs to which haplotypes.

\$haploBlock Marker genotype of haplotype block of interest for the representing haplotypes.

\$pValChi2Test A p-value of the chi-square test for the dependency between haplotypes & subpopulations. If 'chi2Test = FALSE', 'NA' will be returned.

\$mstResults A list of estimated results of MST / MSN / RMST:

Estimated results of MST / MSN / RMST for the data including original haplotypes.

\$mstResComp Estimated results of MST / MSN / RMST for the data including both original and complemented haplotype.

\$distMats A list of distance matrix:

Distance matrix between haplotypes.

\$distMatComp Distance matrix between haplotypes (including unobserved ones).

\$laplacianMat Laplacian matrix between haplotypes (including unobserved ones).

\$gvTotal Estimated genotypic values by kernel regression for each haplotype.

\$gvTotalForLine Estimated genotypic values by kernel regression for each individual.

\$minuslog10p $-\log_{10}(p)$ for haplotype block of interest. p is the p-value for the significance of the haplotype block effect.

\$hOpts Optimized hyper parameters, hOpt1 & hOpt2.

\$EMMResults A list of estimated results of kernel regression:

Estimated results of kernel regression for the estimation of haplotype effects. (1st step)

\$EMMRes Estimated results of kernel regression for the estimation of haplotype effects of nodes. (2nd step)

\$EMM0Res Estimated results of kernel regression for the null model.

\$clusterNosForHaplotype A list of cluster Nos of individuals that belong to each haplotype.

estPhylo

Function to estimate & plot phylogenetic tree

Description

Function to estimate & plot phylogenetic tree

Usage

```

)

```

Arguments

- | | |
|----------------------|---|
| blockInterest | A $n \times M$ matrix representing the marker genotype that belongs to the haplotype block of interest. If this argument is NULL, this argument will automatically be determined by 'geno'. |
| gwasRes | You can use the results (data.frame) of haplotype-based (SNP-set) GWAS by 'RGWAS.multisnp' function. |

nTopRes	Haplotype blocks (or gene sets, SNP-sets) with top 'nTopRes' p-values by 'gwas-Res' will be used.
gene.set	If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
indexRegion	You can specify the haplotype block (or gene set, SNP-set) of interest by the marker index in 'geno'.
chrInterest	You can specify the haplotype block (or gene set, SNP-set) of interest by the marker position in 'geno'. Please assign the chromosome number to this argument.
posRegion	You can specify the haplotype block (or gene set, SNP-set) of interest by the marker position in 'geno'. Please assign the position in the chromosome to this argument.
blockName	You can specify the haplotype block (or gene set, SNP-set) of interest by the name of haplotype block in 'geno'.
pheno	Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
geno	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.
ZETA	<p>A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,</p> <p>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</p> <p>Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.</p> <p>K.A, K.D Different kernels which express some relationships between lines.</p> <p>For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.</p>
chi2Test	If TRUE, chi-square test for the relationship between haplotypes & subpopulations will be performed.
thresChi2Test	The threshold for the chi-square test.
plotTree	If TRUE, the function will return the plot of phylogenetic tree.
distMat	You can assign the distance matrix of the block of interest. If NULL, the distance matrix will be computed in this function.
distMethod	You can choose the method to calculate distance between accessions. This argument corresponds to the 'method' argument in the 'dist' function.
evolutionDist	If TRUE, the evolution distance will be used instead of the pure distance. The 'distMat' will be converted to the distance matrix by the evolution distance.
subpopInfo	The information of subpopulations. This argument should be a vector of factor.
groupingMethod	If 'subpopInfo' argument is NULL, this function estimates subpopulation information from marker genotype. You can choose the grouping method from 'kmeans', 'kmedoids', and 'hclust'.

nGrp	The number of groups (or subpopulations) grouped by 'groupingMethod'. If this argument is 0, the subpopulation information will not be estimated.
nIterClustering	If 'groupingMethod' = 'kmeans', the clustering will be performed multiple times. This argument specifies the number of classification performed by the function.
kernelTypes	In the function, similarity matrix between accessions will be computed from marker genotype to estimate genotypic values. This argument specifies the method to compute similarity matrix: If this argument is 'addNOIA' (or one of other options in 'methodGRM' in 'calcGRM'), then the 'addNOIA' (or corresponding) option in the 'calcGRM' function will be used, and if this argument is 'phylo', the gaussian kernel based on phylogenetic distance will be computed from phylogenetic tree. You can assign more than one kernelTypes for this argument; for example, kernelTypes = c("addNOIA", "phylo").
nCores	The number of cores used for optimization.
hOpt	Optimized hyper parameter for constructing kernel when estimating haplotype effects. If hOpt = "optimized", hyper parameter will be optimized in the function. If hOpt = "tuned", hyper parameter will be replaced by the median of off-diagonal of distance matrix. If hOpt is numeric, that value will be directly used in the function.
hOpt2	Optimized hyper parameter for constructing kernel when estimating haplotype effects of nodes. If hOpt2 = "optimized", hyper parameter will be optimized in the function. If hOpt2 = "tuned", hyper parameter will be replaced by the median of off-diagonal of distance matrix. If hOpt2 is numeric, that value will be directly used in the function.
maxIter	Max number of iterations for optimization algorithm.
rangeHStart	The median of off-diagonal of distance matrix multiplied by rangeHStart will be used as the initial values for optimization of hyper parameters.
saveName	When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.
saveStyle	This argument specifies how to save the plot of phylogenetic tree. The function offers 'png', 'pdf', 'jpg', and 'tiff'.
pchBase	A vector of two integers specifying the plot types for the positive and negative genotypic values respectively.
colNodeBase	A vector of two integers or chracters specifying color of nodes for the positive and negative genotypic values respectively.
colTipBase	A vector of integers or chracters specifying color of tips for the positive and negative genotypic values respectively. The length of the vector should equal to the number of subpopulations.
cexMax	A numeric specifying the maximum point size of the plot.
cexMin	A numeric specifying the minimum point size of the plot.
edgeColoring	If TRUE, the edge branch of phylogenetic tree will be colored.
tipLabel	If TRUE, levels for tips will be shown.
ggPlotTree	If TRUE, the function will return the ggplot version of phylogenetic tree. It offers the precise information on subgroups for each haplotype.
cexMaxForGG	A numeric specifying the maximum point size of the plot for ggtree, relative to the range of x and y-axes ($0 < \text{cexMaxForGG} \leq 1$).

cexMinForGG	A numeric specifying the minimum point size of the plot for ggtree, relative to the range of x and y-axes ($0 < \text{cexMaxForGG} \leq 1$).
alphaBase	alpha (parameter that indicates the opacity of a geom) for tip with positive / negative effects. alpha for node will be same as the alpha for tip with negative effects.
verbose	If this argument is TRUE, messages for the current step_s will be shown.

Value

A list / lists of

A list of haplotype information with

\$haploTypeID A vector indicating each individual belongs to which haplotypes.

\$haploBlock Marker genotype of haplotype block of interest for the representing haplotypes.

\$distMats A list of distance matrix:

Distance matrix between haplotypes.

\$distMatEvol Evolutionary distance matrix between haplotypes.

\$distMatNJ Phylogenetic distance matrix between haplotypes including nodes.

\$pValChi2Test A p-value of the chi-square test for the dependency between haplotypes & subpopulations. If 'chi2Test = FALSE', 'NA' will be returned.

\$njRes The result of phylogenetic tree by neighborhood-joining method

\$gvTotal Estimated genotypic values by kernel regression for each haplotype.

\$gvTotalForLine Estimated genotypic values by kernel regression for each individual.

\$minuslog10p $-\log_{10}(p)$ for haplotype block of interest. p is the p-value for the significance of the haplotype block effect.

\$hOpts Optimized hyper parameters, hOpt1 & hOpt2.

\$EMMResults A list of estimated results of kernel regression:

Estimated results of kernel regression for the estimation of haplotype effects. (1st step)

\$EMM3Res Estimated results of kernel regression for the estimation of haplotype effects of nodes. (2nd step)

\$EMM0Res Estimated results of kernel regression for the null model.

\$clusterNosForHaplotype A list of cluster Nos of individuals that belong to each haplotype.

genesetmap

Function to generate map for gene set

Description

Function to generate map for gene set

Usage

```
genesetmap(map, gene.set, cumulative = FALSE)
```

Arguments

map	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.
gene.set	Gene information with the format of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "map" argument.
cumulative	If this argument is TRUE, cumulative position will be returned.

Value

Map for gene set.

genetrait	<i>Generate pseudo phenotypic values</i>
-----------	--

Description

This function generates pseudo phenotypic values according to the following formula.

$$y = X\beta + Zu + e$$

where effects of major genes are regarded as fixed effects β and polygenetic effects are regarded as random effects u . The variances of u and e are automatically determined by the heritability.

Usage

```
genetrait(
  x,
  sample.sets = NULL,
  candidate = NULL,
  pos = NULL,
  x.par = NULL,
  ZETA = NULL,
  x2 = NULL,
  num.qtn = 3,
  weight = c(2, 1, 1),
  qtn.effect = rep("A", num.qtn),
  prop = 1,
  polygene.weight = 1,
  polygene = TRUE,
  h2 = 0.6,
  h.correction = FALSE,
  seed = NULL,
  plot = TRUE,
  saveAt = NULL,
  subpop = NULL,
  return.all = FALSE,
  seed.env = TRUE
)
```

Arguments

<code>x</code>	A $n.sample \times n.mark$ genotype matrix where <code>n.sample</code> is sample size and <code>n.mark</code> is the number of markers.
<code>sample.sets</code>	A $n.sample \times n.mark$ genotype matrix. Markers with fixed effects (QTNs) are chosen from <code>sample.sets</code> . If <code>sample.sets = NULL</code> , <code>sample.sets = x</code> .
<code>candidate</code>	If you want to fix QTN positions, please set the number where SNPs to be fixed are located in your data (so not position). If <code>candidate = NULL</code> , QTNs were randomly sampled from <code>sample.sets</code> or <code>x</code> .
<code>pos</code>	A $n.mark \times 1$ vector. Cumulative position (over chromosomes) of each marker.
<code>x.par</code>	If you don't want to match the sampling population and the genotype data to QTN effects, then use this argument as the latter.
<code>ZETA</code>	<p>A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,</p> <p><code>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</code></p> <p>Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.</p> <p>K.A, K.D Different kernels which express some relationships between lines. For example, <code>K.A</code> is additive relationship matrix for the covariance between lines, and <code>K.D</code> is dominance relationship matrix.</p>
<code>x2</code>	A genotype matrix to calculate additive relationship matrix when <code>Z.ETA = NULL</code> . If <code>Z.ETA = NULL</code> & <code>x2 = NULL</code> , <code>calcGRM(x)</code> will be calculated as kernel matrix.
<code>num.qtn</code>	The number of QTNs
<code>weight</code>	The weights for each QTN by their standard deviations. Negative value is also allowed.
<code>qtn.effect</code>	Additive of dominance for each marker effect. This argument should be the same length as <code>num.qtn</code> .
<code>prop</code>	The proportion of effects of QTNs to polygenetic effects.
<code>polygene.weight</code>	If there are multiple kernels, this argument determines the weights of each kernel effect.
<code>polygene</code>	If <code>polygene = FALSE</code> , pseudo phenotypes with only QTN effects will be generated.
<code>h2</code>	The wide-sense heritability for generating phenotypes. $0 \leq h2 < 1$
<code>h.correction</code>	If <code>TRUE</code> , this function will generate phenotypes to match the genomic heritability and " <code>h2</code> ".
<code>seed</code>	If <code>seed</code> is not <code>NULL</code> , some fixed phenotypic values will be generated according to <code>set.seed(seed)</code>
<code>plot</code>	If <code>TRUE</code> , boxplot for generated phenotypic values will be drawn.
<code>saveAt</code>	When drawing any plot, you can save plots in png format. In <code>saveAt</code> , you should substitute the name you want to save. When <code>saveAt = NULL</code> , the plot is not saved.
<code>subpop</code>	If there is subpopulation structure, you can draw boxplots divide by subpopulations. $n.sample \times n.subpop$ matrix. Please indicate the subpopulation information by (0, 1) for each element. (0 means that line doesn't belong to that subpopulation, and 1 means that line belongs to that subpopulation)

<code>return.all</code>	If FALSE, only returns generated phenotypic values. If TRUE, this function will return other information such as positions of candidate QTNs.
<code>seed.env</code>	If TRUE, this function will generate different environment effects every time.

Value

trait	Generated phenotypic values
u	Generated genotype values
e	Generated environmental effects
candidate	The numbers where QTNs are located in your data (so not position).
qtn.position	QTN positions
heritability	Genomic heritability for generated phenotypic values.

MAF.cut	<i>Function to remove the minor alleles</i>
---------	---

Description

Function to remove the minor alleles

Usage

```
MAF.cut(x.0, map.0 = NULL, min.MAF = 0.05, max.MS = 0.05, return.MAF = FALSE)
```

Arguments

<code>x.0</code>	A $n \times m$ original marker genotype matrix.
<code>map.0</code>	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.
<code>min.MAF</code>	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is removed from the original marker genotype data.
<code>max.MS</code>	Specifies the maximum missing rate (MS). If a marker has a MS more than max.MS, it is removed from the original marker genotype data.
<code>return.MAF</code>	If TRUE, MAF will be returned.

Value

\$x	The modified marker genotype data whose SNPs with $MAF \leq min.MAF$ were removed.
\$map	The modified map information whose SNPs with $MAF \leq min.MAF$ were removed.
\$before	Minor allele frequencies of the original marker genotype.
\$after	Minor allele frequencies of the modified marker genotype.

make.full	<i>Change a matrix to full-rank matrix</i>
-----------	--

Description

Change a matrix to full-rank matrix

Usage

```
make.full(X)
```

Arguments

X A $n \times p$ matrix which you want to change into full-rank matrix.

Value

A full-rank matrix

manhattan	<i>Draw manhattan plot</i>
-----------	----------------------------

Description

Draw manhattan plot

Usage

```
manhattan(
  input,
  sig.level = 0.05,
  method.thres = "BH",
  y.max = NULL,
  cex = 1,
  cex.lab = 1,
  lwd.thres = 1,
  plot.col1 = c("dark blue", "cornflowerblue"),
  cex.axis.x = 1,
  cex.axis.y = 1,
  plot.type = "p",
  plot.pch = 16
)
```

Arguments

input	Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the fourth column is $-\log_{10}(p)$ for each marker.
sig.level	Significance level for the threshold. The default is 0.05.
method.thres	Method for determining threshold of significance. "BH" and "Bonferroni" are offered.
y.max	The maximum value for the vertical axis of manhattan plot. If NULL, automatically determined.
cex	A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default.
cex.lab	The font size of the labels.
lwd.thres	The line width for the threshold.
plot.col1	This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. plot.col1[1] for odd chromosomes and plot.col1[2] for even chromosomes.
cex.axis.x	The font size of the x axis.
cex.axis.y	The font size of the y axis.
plot.type	This argument determines the type of the manhattan plot. See the help page of "plot".
plot.pch	This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

Value

Draw manhattan plot

manhattan.plus	<i>Add points of $-\log_{10}(p)$ corrected by kernel methods to manhattan plot</i>
----------------	---

Description

Add points of $-\log_{10}(p)$ corrected by kernel methods to manhattan plot

Usage

```
manhattan.plus(
  input,
  checks,
  cex = 1,
  plot.col1 = c("dark blue", "cornflowerblue"),
  plot.col3 = c("red3", "orange3"),
  plot.type = "p",
  plot.pch = 16
)
```

Arguments

<code>input</code>	Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the fourth column is $-\log_{10}(p)$ for each marker.
<code>checks</code>	The marker numbers whose $-\log_{10}(p)$ s are corrected by kernel methods.
<code>cex</code>	A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default.
<code>plot.col1</code>	This argument determines the color of the manhattan plot. You should substitute this argument as a color vector whose length is 2. <code>plot.col1[1]</code> for odd chromosomes and <code>plot.col1[2]</code> for even chromosomes.
<code>plot.col3</code>	Color of $-\log_{10}(p)$ corrected by kernel methods. <code>plot.col3[1]</code> for odd chromosomes and <code>plot.col3[2]</code> for even chromosomes.
<code>plot.type</code>	This argument determines the type of the manhattan plot. See the help page of "plot".
<code>plot.pch</code>	This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".

Value

Draw manhattan plot

manhattan2

Draw manhattan plot (another method)

Description

Draw manhattan plot (another method)

Usage

```
manhattan2(
  input,
  sig.level = 0.05,
  method.thres = "BH",
  cex = 1,
  plot.col2 = 1,
  plot.type = "p",
  plot.pch = 16,
  cum.pos = NULL,
  lwd.thres = 1,
  cex.lab = 1,
  cex.axis = 1
)
```

Arguments

input	Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the fourth column is $-\log_{10}(p)$ for each marker.
sig.level	Significance level for the threshold. The default is 0.05.
method.thres	Method for determining threshold of significance. "BH" and "Bonferroni" are offered.
cex	A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default.
plot.col2	Color of the manhattan plot. color changes with chromosome and it starts from plot.col2 + 1 (so plot.col2 = 1 means color starts from red.)
plot.type	This argument determines the type of the manhattan plot. See the help page of "plot".
plot.pch	This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".
cum.pos	Cumulative position (over chromosomes) of each marker
lwd.thres	The line width for the threshold.
cex.lab	The font size of the labels.
cex.axis	The font size of the axes.

Value

Draw manhattan plot

manhattan3

Draw the effects of epistasis (3d plot and 2d plot)

Description

Draw the effects of epistasis (3d plot and 2d plot)

Usage

```
manhattan3(
  input,
  cum.pos,
  plot.epi.3d = TRUE,
  plot.epi.2d = TRUE,
  main.epi.3d = NULL,
  main.epi.2d = NULL,
  saveName = NULL
)
```

Arguments

input	Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome and map position, and the fourth column is $-\log_{10}(p)$ for each marker.
cum.pos	Cumulative position (over chromosomes) of each marker
plot.epi.3d	If TRUE, draw 3d plot
plot.epi.2d	If TRUE, draw 2d plot
main.epi.3d	The title of 3d plot. If this argument is NULL, trait name is set as the title.
main.epi.2d	The title of 2d plot. If this argument is NULL, trait name is set as the title.
saveName	When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveAt = NULL, the plot is not saved.

Value

Draw 3d plot and 2d plot to show epistatic effects

modify.data	<i>Function to modify genotype and phenotype data to match</i>
-------------	--

Description

Function to modify genotype and phenotype data to match

Usage

```
modify.data(
  pheno.mat,
  geno.mat,
  pheno.labels = NULL,
  geno.names = NULL,
  map = NULL,
  return.ZETA = TRUE,
  return.GWAS.format = FALSE
)
```

Arguments

pheno.mat	A $n_1 \times p$ matrix of phenotype data. rownames(pheno.mat) should be genotype (line; accession; variety) names.
geno.mat	A $n_2 \times m$ matrix of marker genotype data. rownames(geno.mat) should be genotype (line; accession; variety) names.
pheno.labels	A vector of genotype (line; accession; variety) names which correspond to phenotypic values.
geno.names	A vector of genotype (line; accession; variety) names for marker genotype data (duplication is not recommended).
map	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position.

return.ZETA If this argument is TRUE, the list for mixed model equation (ZETA) will be returned.

return.GWAS.format If this argument is TRUE, phenotype and genotype data for GWAS will be returned.

Value

\$geno.modi The modified marker genotype data.

\$pheno.modi The modified phenotype data.

\$ZETA The list for mixed model equation (ZETA).

\$pheno.GWAS GWAS formatted phenotype data.

\$geno.GWAS GWAS formatted marker genotype data.

qq	<i>Draw qq plot</i>
----	---------------------

Description

Draw qq plot

Usage

```
qq(scores)
```

Arguments

scores A vector of $-\log_{10}(p)$ for each marker

Value

Draw qq plot

RAINBOWR	<i>RAINBOWR: Perform Genome-Wide Association Study (GWAS) By Kernel-Based Methods</i>
----------	---

Description

By using 'RAINBOWR' (Reliable Association Inference By Optimizing Weights with R), users can test multiple SNPs (Single Nucleotide Polymorphisms) simultaneously by kernel-based (SNP-set) methods. Users can test not only additive effects but also dominance and epistatic effects. In detail, please check our preprint on bioRxiv: Kosuke Hamazaki and Hiroyoshi Iwata (2019) <doi:10.1101/612028>.

RGWAS.epistasis	<i>Check epistatic effects by kernel-based GWAS (genome-wide association studies)</i>
-----------------	---

Description

Check epistatic effects by kernel-based GWAS (genome-wide association studies)

Usage

```
RGWAS.epistasis(
  pheno,
  geno,
  ZETA = NULL,
  covariate = NULL,
  covariate.factor = NULL,
  structure.matrix = NULL,
  n.PC = 0,
  min.MAF = 0.02,
  n.core = 1,
  test.method = "LR",
  dominance.eff = TRUE,
  haplotype = TRUE,
  num.hap = NULL,
  window.size.half = 5,
  window.slide = 1,
  chi0.mixture = 0.5,
  optimizer = "nllminb",
  gene.set = NULL,
  plot.epi.3d = TRUE,
  plot.epi.2d = TRUE,
  main.epi.3d = NULL,
  main.epi.2d = NULL,
  saveName = NULL,
  verbose = TRUE,
  verbose2 = FALSE,
  count = TRUE,
  time = TRUE
)
```

Arguments

pheno	Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
geno	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.
ZETA	A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example, ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))

	Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.
	K.A, K.D Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.
covariate	A $n \times 1$ vector or a $n \times p_1$ matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.
covariate.factor	A $n \times p_2$ dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.
structure.matrix	You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with n.PC > 0.
n.PC	Number of principal components to include as fixed effects. Default is 0 (equals K model).
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
n.core	Setting n.core > 1 will enable parallel execution on a machine with multiple cores (use only at UNIX command line).
test.method	RGWAS supports two methods to test effects of each SNP-set. "LR" Likelihood-ratio test, relatively slow, but accurate (default). "score" Score test, much faster than LR, but sometimes overestimate $-\log_{10}(p)$.
dominance.eff	If this argument is TRUE, dominance effect is included in the model, and additive x dominance and dominance x dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.
window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
window.slide	This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = $2 * \text{window.size.half} + 1$.
chi0.mixture	RAINBOWR assumes the deviance is considered to follow a $\chi^2(df=0) + (1 - a) \times \chi^2(df=r)$, where r is the degree of freedom. The argument chi0.mixture is a $(0 \leq a < 1)$, and default is 0.5.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlnminb" functions.

<code>gene.set</code>	If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to <code>gene.set</code> in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
<code>plot.epi.3d</code>	If TRUE, draw 3d plot
<code>plot.epi.2d</code>	If TRUE, draw 2d plot
<code>main.epi.3d</code>	The title of 3d plot. If this argument is NULL, trait name is set as the title.
<code>main.epi.2d</code>	The title of 2d plot. If this argument is NULL, trait name is set as the title.
<code>saveName</code>	When drawing any plot, you can save plots in png format. In <code>saveName</code> , you should substitute the name you want to save. When <code>saveName</code> = NULL, the plot is not saved.
<code>verbose</code>	If this argument is TRUE, messages for the current steps will be shown.
<code>verbose2</code>	If this argument is TRUE, welcome message will be shown.
<code>count</code>	When <code>count</code> is TRUE, you can know how far RGWAS has ended with percent display.
<code>time</code>	When <code>time</code> is TRUE, you can know how much time it took to perform RGWAS.

Value

\$map Map information for SNPs which are tested epistatic effects.

\$scores **\$scores** This is the matrix which contains $-\log_{10}(p)$ calculated by the test about epistasis effects.

\$x, \$y The information of the positions of SNPs detected by regular GWAS. These vectors are used when drawing plots. Each output correspond to the replication of row and column of scores.

\$z This is a vector of `$scores`. This vector is also used when drawing plots.

RGWAS.menu

Print the R code which you should perform for RAINBOWR GWAS

Description

Print the R code which you should perform for RAINBOWR (Reliable Association INference By Optimizing Weights with R).

Usage

RGWAS.menu()

Value

The R code which you should perform for RAINBOWR GWAS

RGWAS.multisnp

Testing multiple SNPs simultaneously for GWAS

Description

This function performs SNP-set GWAS (genome-wide association studies), which tests multiple SNPs (single nucleotide polymorphisms) simultaneously. The model of SNP-set GWAS is

$$y = X\beta + Qv + Z_c u_c + Z_r u_r + \epsilon,$$

where y is the vector of phenotypic values, $X\beta$ and Qv are the terms of fixed effects, $Z_c u_c$ and $Z_r u_r$ are the term of random effects and e is the vector of residuals. $X\beta$ indicates all of the fixed effects other than population structure, and often this term also plays a role as an intercept. Qv is the term to correct the effect of population structure. $Z_c u_c$ is the term of polygenetic effects, and suppose that u_c follows the multivariate normal distribution whose variance-covariance matrix is the genetic covariance matrix. $u_c \sim MVN(0, K_c \sigma_c^2)$. $Z_r u_r$ is the term of effects for SNP-set of interest, and suppose that u_r follows the multivariate normal distribution whose variance-covariance matrix is the Gram matrix (linear, exponential, or gaussian kernel) calculated from marker genotype which belong to that SNP-set. Therefore, $u_r \sim MVN(0, K_r \sigma_r^2)$. Finally, the residual term is assumed to identically and independently follow a normal distribution as shown in the following equation. $e \sim MVN(0, I\sigma_e^2)$.

Usage

```

RGWAS.multisnp(
  pheno,
  geno,
  ZETA = NULL,
  covariate = NULL,
  covariate.factor = NULL,
  structure.matrix = NULL,
  n.PC = 0,
  min.MAF = 0.02,
  test.method = "LR",
  n.core = 1,
  kernel.method = "linear",
  kernel.h = "tuned",
  haplotype = TRUE,
  num.hap = NULL,
  test.effect = "additive",
  window.size.half = 5,
  window.slide = 1,
  chi0.mixture = 0.5,
  gene.set = NULL,
  weighting.center = TRUE,
  weighting.other = NULL,
  sig.level = 0.05,
  method.thres = "BH",
  plot.qq = TRUE,
  plot.Manhattan = TRUE,
  plot.method = 1,
  plot.col1 = c("dark blue", "cornflowerblue"),
  plot.col2 = 1,
  plot.type = "p",
  plot.pch = 16,
  saveName = NULL,
  main.qq = NULL,
  main.man = NULL,
  plot.add.last = FALSE,
  return.EMM.res = FALSE,
  optimizer = "nlsminb",
  thres = TRUE,
  verbose = TRUE,
  verbose2 = FALSE,
  count = TRUE,
  time = TRUE
)

```

Arguments

pheno	Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
geno	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.

ZETA	<p>A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,</p> <p><code>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</code></p> <p>Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.</p> <p>K.A, K.D Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.</p>
covariate	A $n \times 1$ vector or a $n \times p_1$ matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.
covariate.factor	A $n \times p_2$ dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.
structure.matrix	You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with <code>n.PC > 0</code> .
n.PC	Number of principal components to include as fixed effects. Default is 0 (equals K model).
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
test.method	<p>RGWAS supports two methods to test effects of each SNP-set.</p> <p>"LR" Likelihood-ratio test, relatively slow, but accurate (default).</p> <p>"score" Score test, much faster than LR, but sometimes overestimate $-\log_{10}(p)$.</p>
n.core	Setting <code>n.core > 1</code> will enable parallel execution on a machine with multiple cores (use only at UNIX command line).
kernel.method	<p>It determines how to calculate kernel. There are three methods.</p> <p>"gaussian" It is the default method. Gaussian kernel is calculated by distance matrix.</p> <p>"exponential" When this method is selected, exponential kernel is calculated by distance matrix.</p> <p>"linear" When this method is selected, linear kernel is calculated by NOIA methods for additive GRM.</p> <p>So local genomic relation matrix is regarded as kernel.</p>
kernel.h	The hyper parameter for gaussian or exponential kernel. If <code>kernel.h = "tuned"</code> , this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
haplotype	If the number of lines of your data is large (maybe > 100), you should set <code>haplotype = TRUE</code> . When <code>haplotype = TRUE</code> , haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When <code>haplotype = TRUE</code> , you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make <code>kernel(K.SNP)</code> whose dimension is <code>num.hap x num.hap</code> . When <code>num.hap = NULL</code> (default), <code>num.hap</code> will be set as the maximum number which reflects the difference between lines.

test.effect	Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "aditive+dominance")
window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be $2 * window.size.half + 1$.
window.slide	This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = $2 * window.size.half + 1$.
chi0.mixture	RAINBOWR assumes the deviance is considered to follow a $x \text{ chisq}(df = 0) + (1 - a) \times \text{chisq}(df = r)$, where r is the degree of freedom. The argument chi0.mixture is a $(0 \leq a < 1)$, and default is 0.5.
gene.set	If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) \times 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
weighting.center	In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.
weighting.other	You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.
sig.level	Significance level for the threshold. The default is 0.05.
method.thres	Method for detemining threshold of significance. "BH" and "Bonferroni are offered.
plot.qq	If TRUE, draw qq plot.
plot.Manhattan	If TRUE, draw manhattan plot.
plot.method	If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot's color is changed by all chromosomes.
plot.col1	This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. plot.col1[1] for odd chromosomes and plot.col1[2] for even chromosomes
plot.col2	Color of the manhattan plot. color changes with chromosome and it starts from plot.col2 + 1 (so plot.col2 = 1 means color starts from red.)
plot.type	This argument determines the type of the manhattan plot. See the help page of "plot".
plot.pch	This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".
saveName	When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.
main.qq	The title of qq plot. If this argument is NULL, trait name is set as the title.

<code>main.man</code>	The title of manhattan plot. If this argument is NULL, trait name is set as the title.
<code>plot.add.last</code>	If <code>saveName</code> is not NULL and this argument is TRUE, then you can add lines or dots to manhattan plots. However, you should also write <code>"dev.off()"</code> after adding something.
<code>return.EMM.res</code>	When <code>return.EMM.res = TRUE</code> , the results of equation of mixed models are included in the result of RGWAS.
<code>optimizer</code>	The function used in the optimization process. We offer "optim", "optimx", and "nlopt" functions.
<code>thres</code>	If <code>thres = TRUE</code> , the threshold of the manhattan plot is included in the result of RGWAS. When <code>return.EMM.res</code> or <code>thres</code> is TRUE, the results will be "list" class.
<code>verbose</code>	If this argument is TRUE, messages for the current steps will be shown.
<code>verbose2</code>	If this argument is TRUE, welcome message will be shown.
<code>count</code>	When <code>count</code> is TRUE, you can know how far RGWAS has ended with percent display.
<code>time</code>	When <code>time</code> is TRUE, you can know how much time it took to perform RGWAS.

Details

P-value for each SNP-set is calculated by performing the LR test or the score test (Lippert et al., 2014).

In the LR test, first, the function solves the multi-kernel mixed model and calculates the maximum restricted log likelihood. Then it performs the LR test by using the fact that the deviance

$$D = 2 \times (LL_{alt} - LL_{null})$$

follows the chi-square distribution.

In the score test, the maximization of the likelihood is only performed for the null model. In other words, the function calculates the score statistic without solving the multi-kernel mixed model for each SNP-set. Then it performs the score test by using the fact that the score statistic follows the chi-square distribution.

Value

\$D Dataframe which contains the information of the map you input and the results of RGWAS ($-\log_{10}(p)$) which correspond to the map. If there are more than one test.effects, then multiple lists for each test.effect are returned respectively.

\$thres A vector which contains the information of threshold determined by $FDR = 0.05$.

\$EMM.res This output is a list which contains the information about the results of "EMM" performed at first in regular GWAS. If you want to know details, see the description for the function "EMM1" or "EMM2".

RGWAS.normal

Perform normal GWAS (test each single SNP)

Description

This function performs single-SNP GWAS (genome-wide association studies). The model of GWAS is

$$y = X\beta + S_i\alpha_i + Qv + Zu + \epsilon,$$

where y is the vector of phenotypic values, $X\beta$, $S_i\alpha_i$, Qv are the terms of fixed effects, Zu is the term of random effects and e is the vector of residuals. $X\beta$ indicates all of the fixed effects other than the effect of SNPs to be tested and of population structure, and often this term also plays a role as an intercept. For $S_i\alpha_i$, S_i is the i th marker of genotype data and α_i is the effect of that marker. Qv is the term to correct the effect of population structure. Zu is the term of polygenetic effects, and suppose that u follows the multivariate normal distribution whose variance-covariance matrix is the genetic covariance matrix. $u \sim MVN(0, K\sigma_u^2)$. Finally, the residual term is assumed to identically and independently follow a normal distribution as shown in the following equation. $e \sim MVN(0, I\sigma_e^2)$.

Usage

```

RGWAS.normal(
  pheno,
  geno,
  ZETA = NULL,
  covariate = NULL,
  covariate.factor = NULL,

```

```

structure.matrix = NULL,

plot.pch = 16,
saveName = NULL,
main.qq = NULL,
main.man = NULL,
plot.add.last = FALSE,
return.EMM.res = FALSE,
optimizer = "nlsminb",
thres = TRUE,
verbose = TRUE,
verbose2 = FALSE,
count = TRUE,
time = TRUE
)

```

Arguments

pheno	Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
geno	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.
ZETA	<p>A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,</p> <p>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</p> <p>Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.</p> <p>K.A, K.D Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.</p>
covariate	A $n \times 1$ vector or a $n \times p_1$ matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.
covariate.factor	A $n \times p_2$ dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.

<code>structure.matrix</code>	You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with <code>n.PC > 0</code> .
<code>n.PC</code>	Number of principal components to include as fixed effects. Default is 0 (equals K model).
<code>min.MAF</code>	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than <code>min.MAF</code> , it is assigned a zero score.
<code>P3D</code>	When <code>P3D = TRUE</code> , variance components are estimated by REML only once, without any markers in the model. When <code>P3D = FALSE</code> , variance components are estimated by REML for each marker separately.
<code>n.core</code>	Setting <code>n.core > 1</code> will enable parallel execution on a machine with multiple cores.
<code>sig.level</code>	Significance level for the threshold. The default is 0.05.
<code>method.thres</code>	Method for determining threshold of significance. "BH" and "Bonferroni" are offered.
<code>plot.qq</code>	If TRUE, draw qq plot.
<code>plot.Manhattan</code>	If TRUE, draw manhattan plot.
<code>plot.method</code>	If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot's color is changed by all chromosomes.
<code>plot.col1</code>	This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. <code>plot.col1[1]</code> for odd chromosomes and <code>plot.col1[2]</code> for even chromosomes
<code>plot.col2</code>	Color of the manhattan plot. color changes with chromosome and it starts from <code>plot.col2 + 1</code> (so <code>plot.col2 = 1</code> means color starts from red.)
<code>plot.type</code>	This argument determines the type of the manhattan plot. See the help page of "plot".
<code>plot.pch</code>	This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".
<code>saveName</code>	When drawing any plot, you can save plots in png format. In <code>saveName</code> , you should substitute the name you want to save. When <code>saveName = NULL</code> , the plot is not saved.
<code>main.qq</code>	The title of qq plot. If this argument is NULL, trait name is set as the title.
<code>main.man</code>	The title of manhattan plot. If this argument is NULL, trait name is set as the title.
<code>plot.add.last</code>	If <code>saveName</code> is not NULL and this argument is TRUE, then you can add lines or dots to manhattan plots. However, you should also write <code>"dev.off()"</code> after adding something.
<code>return.EMM.res</code>	When <code>return.EMM.res = TRUE</code> , the results of equation of mixed models are included in the result of RGWAS.
<code>optimizer</code>	The function used in the optimization process. We offer "optim", "optimx", and "nlopt" functions.
<code>thres</code>	If <code>thres = TRUE</code> , the threshold of the manhattan plot is included in the result of RGWAS. When <code>return.EMM.res</code> or <code>thres</code> is TRUE, the results will be "list" class.
<code>verbose</code>	If this argument is TRUE, messages for the current steps will be shown.

verbose2	If this argument is TRUE, welcome message will be shown.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.
time	When time is TRUE, you can know how much time it took to perform RGWAS.

Details

P-value for each marker is calculated by performing F-test against the F-value as follows (Kennedy et al., 1992).

$$F = \frac{(L'\hat{b})'[L'(X'H^{-1}X)^{-1}L]^{-1}(L'\hat{b})}{f\hat{\sigma}_u^2},$$

where b is the vector of coefficients of the fixed effects, which combines β , α_i , v in the horizontal direction and L is a matrix to indicate which effects in b are tested. H is calculated by dividing the estimated variance-covariance matrix for the phenotypic values by σ_u^2 , and is calculated by $H = ZKZ' + \hat{\lambda}I$. $\hat{\lambda}$ is the maximum likelihood estimator of the ratio between the residual variance and the additive genetic variance. \hat{b} is the maximum likelihood estimator of b and is calculated by $\hat{b} = (X'H^{-1}X)^{-1}X'H^{-1}y$. f is the number of the fixed effects to be tested, and $\hat{\sigma}_u^2$ is estimated by the following formula.

$$\hat{\sigma}_u^2 = \frac{(y - X\hat{b})'H^{-1}(y - X\hat{b})}{n - p},$$

where n is the sample size and p is the number of the all fixed effects. We calculated each p-value using the fact that the above F-value follows the F distribution with the degree of freedom $(f, n - p)$.

Value

\$D Dataframe which contains the information of the map you input and the results of RGWAS (-log10(p)) which correspond to the map.

\$thres A vector which contains the information of threshold determined by FDR = 0.05.

\$EMM.res This output is a list which contains the information about the results of "EMM" performed at first in regular GWAS. If you want to know details, see the description for the function "EMM1" or "EMM2".

verbose2 = FALSE,
count = TRUE,
time = TRUE
)

```

Arguments

pheno	Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
geno	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.
ZETA	<p>A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,</p> <p><code>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</code></p> <p>Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.</p> <p>K.A, K.D Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.</p>
covariate	A $n \times 1$ vector or a $n \times p_1$ matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.
covariate.factor	A $n \times p_2$ dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.
structure.matrix	You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with $n.PC > 0$.
n.PC	Number of principal components to include as fixed effects. Default is 0 (equals K model).
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
n.core	Setting $n.core > 1$ will enable parallel execution on a machine with multiple cores (use only at UNIX command line).

check.size	This argument determines how many SNPs (around the SNP detected by normal GWAS) you will recalculate $-\log_{10}(p)$.
check.gene.size	This argument determines how many genes (around the genes detected by normal GWAS) you will recalculate $-\log_{10}(p)$. This argument is valid only when you assign "gene.set" argument.
kernel.percent	This argument determines how many SNPs are detected by normal GWAS. For example, when kernel.percent = 0.1, SNPs whose value of $-\log_{10}(p)$ is in the top 0.1 percent are chosen as candidate for recalculation by SNP-set GWAS.
GWAS.res.first	If you have already performed normal GWAS and have the result, you can skip performing normal GWAS.
P3D	When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.
test.method.1	RGWAS supports two methods to test effects of each SNP-set for 1st GWAS. "normal" Normal GWAS (default). "score" Score test, much faster than LR, but sometimes overestimate $-\log_{10}(p)$.
test.method.2	RGWAS supports two methods to test effects of each SNP-set for 2nd GWAS. "LR" Likelihood-ratio test, relatively slow, but accurate (default). "score" Score test, much faster than LR, but sometimes overestimate $-\log_{10}(p)$.
kernel.method	It determines how to calculate kernel. There are three methods. "gaussian" It is the default method. Gaussian kernel is calculated by distance matrix. "exponential" When this method is selected, exponential kernel is calculated by distance matrix. "linear" When this method is selected, linear kernel is calculated by NOIA methods for additive GRM. So local genomic relation matrix is regarded as kernel.
kernel.h	The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.
test.effect.1	Effect of each marker to test for 1st GWAS. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". you can assign only one test effect for the 1st GWAS!
test.effect.2	Effect of each marker to test for 2nd GWAS. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "aditive+dominance")

<code>window.size.half</code>	This argument decides how many SNPs (around the SNP you want to test) are used to calculate K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
<code>window.slide</code>	This argument determines how often you test markers. If <code>window.slide = 1</code> , every marker will be tested. If you want to perform SNP set by bins, please set <code>window.slide = 2 * window.size.half + 1</code> .
<code>chi0.mixture</code>	RAINBOWR assumes the deviance is considered to follow $a \times \text{chisq}(df = 0) + (1 - a) \times \text{chisq}(df = r)$, where r is the degree of freedom. The argument <code>chi0.mixture</code> is a $(0 \leq a < 1)$, and default is 0.5.
<code>optimizer</code>	The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
<code>gene.set</code>	If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to <code>gene.set</code> in the form of a "data.frame" (whose dimension is (the number of gene) \times 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
<code>weighting.center</code>	In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if <code>Rainbow = TRUE</code> . If <code>weighting.center = FALSE</code> , weights are not taken into account.
<code>weighting.other</code>	You can set other weights in addition to <code>weighting.center</code> . The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.
<code>sig.level</code>	Significance level for the threshold. The default is 0.05.
<code>method.thres</code>	Method for determining threshold of significance. "BH" and "Bonferroni" are offered.
<code>plot.qq.1</code>	If TRUE, draw qq plot for normal GWAS.
<code>plot.Manhattan.1</code>	If TRUE, draw manhattan plot for normal GWAS.
<code>plot.qq.2</code>	If TRUE, draw qq plot for SNP-set GWAS.
<code>plot.Manhattan.2</code>	If TRUE, draw manhattan plot for SNP-set GWAS.
<code>plot.method</code>	If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot's color is changed by all chromosomes.
<code>plot.col1</code>	This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. <code>plot.col1[1]</code> for odd chromosomes and <code>plot.col1[2]</code> for even chromosomes
<code>plot.col2</code>	Color of the manhattan plot. color changes with chromosome and it starts from <code>plot.col2 + 1</code> (so <code>plot.col2 = 1</code> means color starts from red.)
<code>plot.col3</code>	Color of the points of manhattan plot which are added after the reestimation by SNP-set method. You should substitute this argument as color vector whose length is 2. <code>plot.col3[1]</code> for odd chromosomes and <code>plot.col3[2]</code> for even chromosomes.

plot.type	This argument determines the type of the manhattan plot. See the help page of "plot".
plot.pch	This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".
saveName	When drawing any plot, you can save plots in png format. In saveName, you should substitute the name you want to save. When saveName = NULL, the plot is not saved.
main.qq.1	The title of qq plot for normal GWAS. If this argument is NULL, trait name is set as the title.
main.man.1	The title of manhattan plot for normal GWAS. If this argument is NULL, trait name is set as the title.
main.qq.2	The title of qq plot for SNP-set GWAS. If this argument is NULL, trait name is set as the title.
main.man.2	The title of manhattan plot for SNP-set GWAS. If this argument is NULL, trait name is set as the title.
plot.add.last	If saveName is not NULL and this argument is TRUE, then you can add lines or dots to manhattan plots. However, you should also write "dev.off()" after adding something.
return.EMM.res	When return.EMM.res = TRUE, the results of equation of mixed models are included in the result of RGWAS.
thres	If thres = TRUE, the threshold of the manhattan plot is included in the result of RGWAS. When return.EMM.res or thres is TRUE, the results will be "list" class.
verbose	If this argument is TRUE, messages for the current steps will be shown.
verbose2	If this argument is TRUE, welcome message will be shown.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.
time	When time is TRUE, you can know how much time it took to perform RGWAS.

Value

\$D Dataframe which contains the information of the map you input and the results of RGWAS ($-\log_{10}(p)$) which correspond to the map. $-\log_{10}(p)$ by normal GWAS and recalculated $-\log_{10}(p)$ by SNP-set GWAS will be obtained. If there are more than one test.effects, then multiple lists for each test.effect are returned respectively.

\$thres A vector which contains the information of threshold determined by $FDR = 0.05$.

\$EMM.res This output is a list which contains the information about the results of "EMM" performed at first in normal GWAS. If you want to know details, see the description for the function "EMM1" or "EMM2".

RGWAS.twostep.epi	<i>Perform normal GWAS (genome-wide association studies) first, then check epistatic effects for relatively significant markers</i>
-------------------	---

Description

Perform normal GWAS (genome-wide association studies) first, then check epistatic effects for relatively significant markers

Usage

```

RGWAS.twostep.epi(
  pheno,
  geno,
  ZETA = NULL,
  covariate = NULL,
  covariate.factor = NULL,
  structure.matrix = NULL,
  n.PC = 0,
  min.MAF = 0.02,
  n.core = 1,
  check.size.epi = 4,
  epistasis.percent = 0.05,
  check.epi.max = 200,
  your.check = NULL,
  GWAS.res.first = NULL,
  P3D = TRUE,
  test.method = "LR",
  dominance.eff = TRUE,

```

```

haplotype = TRUE,
num.hap = NULL,
optimizer = "nlsminb",
window.size.half = 5,
window.slide = 1,
chi0.mixture = 0.5,
gene.set = NULL,
sig.level = 0.05,
method.thres = "BH",
plot.qq.1 = TRUE,
plot.Manhattan.1 = TRUE,
plot.epi.3d = TRUE,
plot.epi.2d = TRUE,
plot.method = 1,
plot.col1 = c("dark blue", "cornflowerblue"),
plot.col2 = 1,
plot.type = "p",
plot.pch = 16,
saveName = NULL,
main.qq.1 = NULL,
main.man.1 = NULL,
main.epi.3d = NULL,
main.epi.2d = NULL,
verbose = TRUE,
verbose2 = FALSE,
count = TRUE,
time = TRUE
)

```

Arguments

pheno	Data frame where the first column is the line name (gid). The remaining columns should be a phenotype to test.
geno	Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. Columns 4 and higher contain the marker scores for each line, coded as -1, 0, 1 = aa, Aa, AA.
ZETA	<p>A list of covariance (relationship) matrix ($K: m \times m$) and its design matrix ($Z: n \times m$) of random effects. Please set names of list "Z" and "K"! You can use more than one kernel matrix. For example,</p> <p>ZETA = list(A = list(Z = Z.A, K = K.A), D = list(Z = Z.D, K = K.D))</p> <p>Z.A, Z.D Design matrix ($n \times m$) for the random effects. So, in many cases, you can use the identity matrix.</p> <p>K.A, K.D Different kernels which express some relationships between lines. For example, K.A is additive relationship matrix for the covariance between lines, and K.D is dominance relationship matrix.</p>
covariate	A $n \times 1$ vector or a $n \times p_1$ matrix. You can insert continuous values, such as other traits or genotype score for special markers. This argument is regarded as one of the fixed effects.
covariate.factor	A $n \times p_2$ dataframe. You should assign a factor vector for each column. Then RGWAS changes this argument into model matrix, and this model matrix will be included in the model as fixed effects.

structure.matrix	You can use structure matrix calculated by structure analysis when there are population structure. You should not use this argument with n.PC > 0.
n.PC	Number of principal components to include as fixed effects. Default is 0 (equals K model).
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
n.core	Setting n.core > 1 will enable parallel execution on a machine with multiple cores (use only at UNIX command line).
check.size.epi	This argument determines how many SNPs (around the SNP detected by normal GWAS) you will check epistasis.
epistasis.percent	This argument determines how many SNPs are detected by normal GWAS. For example, when epistasis.percent = 0.1, SNPs whose value of -log ₁₀ (p) is in the top 0.1 percent are chosen as candidate for checking epistasis.
check.epi.max	It takes a lot of time to check epistasis, so you can decide the maximum number of SNPs to check epistasis.
your.check	Because there are less SNPs that can be tested in epistasis than in kernel-based GWAS, you can select which SNPs you want to test. If you use this argument, please set the number where SNPs to be tested are located in your data (so not position). In the default setting, your_check = NULL and epistasis between SNPs detected by GWAS will be tested.
GWAS.res.first	If you have already performed regular GWAS and have the result, you can skip performing normal GWAS.
P3D	When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.
test.method	RGWAS supports two methods to test effects of each SNP-set. "LR" Likelihood-ratio test, relatively slow, but accurate (default). "score" Score test, much faster than LR, but sometimes overestimate -log ₁₀ (p).
dominance.eff	If this argument is TRUE, dominance effect is included in the model, and additive x dominance and dominance x dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating -log ₁₀ (p). (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlnmb" functions.
window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculate K.SNP. More precisely, the number of SNPs will be 2 * window.size.half + 1.

<code>window.slide</code>	This argument determines how often you test markers. If <code>window.slide = 1</code> , every marker will be tested. If you want to perform SNP set by bins, please set <code>window.slide = 2 * window.size.half + 1</code> .
<code>chi0.mixture</code>	RAINBOWR assumes the deviance is considered to follow a $x \text{chisq}(df = 0) + (1 - a) \times \text{chisq}(df = r)$, where r is the degree of freedom. The argument <code>chi0.mixture</code> is a $(0 \leq a < 1)$, and default is 0.5.
<code>gene.set</code>	If you have information of gene (or haplotype block), you can use it to perform kernel-based GWAS. You should assign your gene information to <code>gene.set</code> in the form of a "data.frame" (whose dimension is (the number of gene) \times 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
<code>sig.level</code>	Significance level for the threshold. The default is 0.05.
<code>method.thres</code>	Method for detemining threshold of significance. "BH" and "Bonferroni" are offered.
<code>plot.qq.1</code>	If TRUE, draw qq plot for normal GWAS.
<code>plot.Manhattan.1</code>	If TRUE, draw manhattan plot for normal GWAS.
<code>plot.epi.3d</code>	If TRUE, draw 3d plot
<code>plot.epi.2d</code>	If TRUE, draw 2d plot
<code>plot.method</code>	If this argument = 1, the default manhattan plot will be drawn. If this argument = 2, the manhattan plot with axis based on Position (bp) will be drawn. Also, this plot's color is changed by all chromosomes.
<code>plot.col1</code>	This argument determines the color of the manhattan plot. You should substitute this argument as color vector whose length is 2. <code>plot.col1[1]</code> for odd chromosomes and <code>plot.col1[2]</code> for even chromosomes
<code>plot.col2</code>	Color of the manhattan plot. color changes with chromosome and it starts from <code>plot.col2 + 1</code> (so <code>plot.col2 = 1</code> means color starts from red.)
<code>plot.type</code>	This argument determines the type of the manhattan plot. See the help page of "plot".
<code>plot.pch</code>	This argument determines the shape of the dot of the manhattan plot. See the help page of "plot".
<code>saveName</code>	When drawing any plot, you can save plots in png format. In <code>saveName</code> , you should substitute the name you want to save. When <code>saveName = NULL</code> , the plot is not saved.
<code>main.qq.1</code>	The title of qq plot for normal GWAS. If this argument is NULL, trait name is set as the title.
<code>main.man.1</code>	The title of manhattan plot for normal GWAS. If this argument is NULL, trait name is set as the title.
<code>main.epi.3d</code>	The title of 3d plot. If this argument is NULL, trait name is set as the title.
<code>main.epi.2d</code>	The title of 2d plot. If this argument is NULL, trait name is set as the title.
<code>verbose</code>	If this argument is TRUE, messages for the current steps will be shown.
<code>verbose2</code>	If this argument is TRUE, welcome message will be shown.
<code>count</code>	When <code>count</code> is TRUE, you can know how far RGWAS has ended with percent display.
<code>time</code>	When <code>time</code> is TRUE, you can know how much time it took to perform RGWAS.

Value

\$first The results of first normal GWAS will be returned.

\$epistasis \$map Map information for SNPs which are tested epistatic effects.

\$scores \$scores This is the matrix which contains $-\log_{10}(p)$ calculated by the test about epistasis effects.

\$x, \$y The information of the positions of SNPs detected by regular GWAS. These vectors are used when drawing plots. Each output correspond to the replication of row and column of scores.

\$z This is a vector of \$scores. This vector is also used when drawing plots.

Rice_genotype_map

Physical map of rice genome

Description

A dataset containing the information of physical map of rice genome (Zhao et al., 2010; PLoS One 5(5): e10780).

Format

A data frame with 1311 rows and 3 variables:

marker marker name for each marker, character

chr chromosome number for each marker, integer

pos physical position for each marker, integer, (b.p.)

Source

<http://www.ricediversity.org/data/>

References

Rice_genotype_score	<i>Marker genotype of rice genome</i>
---------------------	---------------------------------------

Description

A dataset containing the information of marker genotype (scored with -1, 0, 1) of rice genome (Zhao et al., 2010; PLoS One 5(5): e10780).

Format

A data frame with 1311 rows and 395 variables:

Each column shows the marker genotype of each accession. The column names are the names of accessions and the rownames are the names of markers.

Source

Rice_pheno

Phenotype data of rice field trial

Description

A dataset containing the information of phenotype data of rice field trial (Zhao et al., 2011; Nat Comm 2:467).

Format

A data frame with 413 rows and 36 variables:

Phenotypic data of 36 traits obtained by the field trial with 413 genotypes.

Source

<http://www.ricediversity.org/data/>

References

Zhao, K. et al. (2011) Genome-wide association mapping reveals a rich genetic architecture of complex traits in *Oryza sativa*. Nat Commun. 2: 467.

Rice_Zhao_etal

Rice_Zhao_etal:

Description

A list containing the information of marker genotype of rice genome (Zhao et al., 2010; PLoS One 5(5): e10780) and phenotype data of rice field trial (Zhao et al., 2011; Nat Comm 2:467).

Usage

Rice_Zhao_etal

Format

A list of 3 data frames:

\$genoScore marker genotype, [Rice_geno_score](#)

\$genoMap physical map, [Rice_geno_map](#)

\$pheno phenotype, [Rice_pheno](#)

Details

Marker genotype and phenotype data of rice by Zhao et al., 2010.

score.calc

Calculate -log10(p) for single-SNP GWAS

Description

Calculate -log10(p) of each SNP by the Wald test.

Usage

```
score.calc(
  M.now,
  ZETA.now,
  y,
  X.now,
  Hinv,
  P3D = TRUE,
  optimizer = "nlminb",
  eigen.G = NULL,
  min.MAF = 0.02,
  count = TRUE
)
```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
ZETA.now	A list of variance (relationship) matrix ($K; m \times m$) and its design matrix ($Z; n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
Hinv	The inverse of $H = ZKZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$.
P3D	When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.

eigen.G	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ for each marker

score.calc.epistasis.LR

Calculate $-\log_{10}(p)$ of epistatic effects by LR test

Description

Calculate $-\log_{10}(p)$ of epistatic effects by LR test

Usage

```
score.calc.epistasis.LR(
  M.now,
  y,
  X.now,
  ZETA.now,
  eigen.SGS = NULL,
  eigen.G = NULL,
  optimizer = "nllminb",
  map,
  haplotype = TRUE,
  num.hap = NULL,
  window.size.half = 5,
```

```

window.slide = 1,
chi0.mixture = 0.5,
gene.set = NULL,
dominance.eff = TRUE,
min.MAF = 0.02,
count = TRUE
)

```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA.now	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
eigen.SGS	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of SGS, where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
eigen.G	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
map	Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is $-\log_{10}(p)$ for each marker.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K .SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculate K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
window.slide	This argument determines how often you test markers. If <code>window.slide = 1</code> , every marker will be tested. If you want to perform SNP set by bins, please set <code>window.slide = 2 * window.size.half + 1</code> .
chi0.mixture	RAINBOWR assumes the tdeviance is considered to follow $a \times \text{chisq}(df = 0) + (1 - a) \times \text{chisq}(df = r)$, where r is the degree of freedom. The argument <code>chi0.mixture</code> is a ($0 \leq a < 1$), and default is 0.5.
gene.set	If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to <code>gene.set</code> in the form of a "data.frame" (whose dimension is (the number of gene) \times 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
dominance.eff	If this argument is TRUE, dominance effect is included in the model, and additive \times dominance and dominance \times dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than <code>min.MAF</code> , it is assigned a zero score.
count	When <code>count</code> is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ of epistatic effects for each SNP-set

score.calc.epistasis.score

Calculate $-\log_{10}(p)$ of epistatic effects with score test

Description

Calculate $-\log_{10}(p)$ of epistatic effects with score test

Usage

```
score.calc.epistasis.score(
  M.now,
  y,
  X.now,
  ZETA.now,
  Gu,
  Ge,
  P0,
  map,
  haplotype = TRUE,
  num.hap = NULL,
  window.size.half = 5,
  window.slide = 1,
  chi0.mixture = 0.5,
  gene.set = NULL,
  dominance.eff = TRUE,
  min.MAF = 0.02,
  count = TRUE
)
```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA.now	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, <code>ZETA = list(A = list(Z = Z, K = K))</code> Please set names of list "Z" and "K"!
Gu	A $n \times n$ matrix. You should assign ZKZ' , where K is covariance (relationship) matrix and Z is its design matrix.
Ge	A $n \times n$ matrix. You should assign identity matrix I (diag(n)).
P0	A $n \times n$ matrix. The Moore-Penrose generalized inverse of $SV0S$, where $S = X(X'X)^{-1}X'$ and $V0 = \sigma_u^2 Gu + \sigma_e^2 Ge$. σ_u^2 and σ_e^2 are estimators of the null model.
map	Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is $-\log_{10}(p)$ for each marker.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.

window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculate K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
window.slide	This argument determines how often you test markers. If <code>window.slide = 1</code> , every marker will be tested. If you want to perform SNP set by bins, please set <code>window.slide = 2 * window.size.half + 1</code> .
chi0.mixture	RAINBOWR assumes the test statistic $l1'Fl1$ is considered to follow a χ^2 distribution with $df = 0 + (1 - a) \times \chi^2(df = r)$, where $l1$ is the first derivative of the log-likelihood and F is the Fisher information. And r is the degree of freedom. The argument <code>chi0.mixture</code> is a $(0 \leq a < 1)$, and default is 0.5.
gene.set	If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to <code>gene.set</code> in the form of a "data.frame" (whose dimension is (the number of gene) \times 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
dominance.eff	If this argument is TRUE, dominance effect is included in the model, and additive \times dominance and dominance \times dominance are also tested as epistatic effects. When you use inbred lines, please set this argument FALSE.
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ of epistatic effects for each SNP-set

References

- Listgarten, J. et al. (2013) A powerful and efficient set test for genetic markers that handles confounders. *Bioinformatics*. 29(12): 1526-1533.

score.calc.LR	<i>Calculate $-\log_{10}(p)$ of each SNP-set by the LR test</i>
---------------	--

Description

This function calculates $-\log_{10}(p)$ of each SNP-set by the LR (likelihood-ratio) test. First, the function solves the multi-kernel mixed model and calculates the maximum restricted log likelihood. Then it performs the LR test by using the fact that the deviance

$$D = 2 \times (LL_{alt} - LL_{null})$$

follows the chi-square distribution.

Usage

```
score.calc.LR(
  M.now,
  y,
  X.now,
  ZETA.now,
  LL0,
  eigen.SGS = NULL,
  eigen.G = NULL,
  optimizer = "nllminb",
  map,
  kernel.method = "linear",
  kernel.h = "tuned",
  haplotype = TRUE,
  num.hap = NULL,
  test.effect = "additive",
  window.size.half = 5,
  window.slide = 1,
  chi0.mixture = 0.5,
  weighting.center = TRUE,
  weighting.other = NULL,
  gene.set = NULL,
  min.MAF = 0.02,
  count = TRUE
)
```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA.now	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
LL0	The log-likelihood for the null model.
eigen.SGS	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of SGS, where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
eigen.G	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p>

	The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlnmb" functions.
map	Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the fourth column is $-\log_{10}(p)$ for each marker.
kernel.method	It determines how to calculate kernel. There are three methods. "gaussian" It is the default method. Gaussian kernel is calculated by distance matrix. "exponential" When this method is selected, exponential kernel is calculated by distance matrix. "linear" When this method is selected, linear kernel is calculated by NOIA methods for additive GRM.
kernel.h	The hyper-parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.
test.effect	Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "additive+dominance")
window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculate K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
window.slide	This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = $2 * \text{window.size.half} + 1$.
chi0.mixture	RAINBOWR assumes the deviance is considered to follow $a \times \text{chisq}(df = 0) + (1 - a) \times \text{chisq}(df = r)$, where r is the degree of freedom. The argument chi0.mixture is a $(0 \leq a < 1)$, and default is 0.5.
weighting.center	In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.
weighting.other	You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.

gene.set	If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ for each SNP-set

References

Listgarten, J. et al. (2013) A powerful and efficient set test for genetic markers that handles confounders. *Bioinformatics*. 29(12): 1526-1533.

score.calc.LR.MC	<i>Calculate $-\log_{10}(p)$ of each SNP-set by the LR test (multi-cores)</i>
------------------	--

Description

This function calculates $-\log_{10}(p)$ of each SNP-set by the LR (likelihood-ratio) test. First, the function solves the multi-kernel mixed model and calculates the maximum restricted log likelihood. Then it performs the LR test by using the fact that the deviance

$$D = 2 \times (LL_{alt} - LL_{null})$$

follows the chi-square distribution.

Usage

```
score.calc.LR.MC(
  M.now,
  y,
  X.now,
  ZETA.now,
  LL0,
  eigen.SGS = NULL,
  eigen.G = NULL,
  n.core = 2,
  map,
  kernel.method = "linear",
  kernel.h = "tuned",
  haplotype = TRUE,
  num.hap = NULL,
```

```

test.effect = "additive",
window.size.half = 5,
window.slide = 1,
optimizer = "nlnmb",
chi0.mixture = 0.5,
weighting.center = TRUE,
weighting.other = NULL,
gene.set = NULL,
min.MAF = 0.02,
count = TRUE
)

```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA.now	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
LL0	The log-likelihood for the null model.
eigen.SGS	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of SGS, where $S = I - X(X'X)^{-1}X'$, $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
eigen.G	<p>A list with</p> <p>\$values Eigen values</p> <p>\$vectors Eigen vectors</p> <p>The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.</p>
n.core	Setting n.core > 1 will enable parallel execution on a machine with multiple cores.
map	Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is -log10(p) for each marker.
kernel.method	<p>It determines how to calculate kernel. There are three methods.</p> <p>"gaussian" It is the default method. Gaussian kernel is calculated by distance matrix.</p> <p>"exponential" When this method is selected, exponential kernel is calculated by distance matrix.</p>

	"linear" When this method is selected, linear kernel is calculated by NOIA methods for additive GRM.
kernel.h	The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.
test.effect	Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "aditive+dominance")
window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
window.slide	This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = $2 * \text{window.size.half} + 1$.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlnmb" functions.
chi0.mixture	RAINBOWR assumes the deviance is considered to follow $a \times \text{chisq}(df = 0) + (1 - a) \times \text{chisq}(df = r)$, where r is the degree of freedom. The argument chi0.mixture is a $(0 \leq a < 1)$, and default is 0.5.
weighting.center	In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.
weighting.other	You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.
gene.set	If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ for each SNP-set

References

score.calc.MC	<i>Calculate -log10(p) for single-SNP GWAS (multi-cores)</i>
---------------	--

Description

Calculate -log10(p) of each SNP by the Wald test.

Usage

```
score.calc.MC(
  M.now,
  ZETA.now,
  y,
  X.now,
  Hinv,
  n.core = 2,
  P3D = TRUE,
  optimizer = "nlminb",
  eigen.G = NULL,
  min.MAF = 0.02,
  count = TRUE
)
```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
ZETA.now	A list of variance (relationship) matrix ($K; m \times m$) and its design matrix ($Z; n \times m$) of random effects. You can use only one kernel matrix. For example, <code>ZETA = list(A = list(Z = Z, K = K))</code> Please set names of list "Z" and "K"!
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (<code>rep(1, n)</code>) and covariates. NA is not allowed.
Hinv	The inverse of $H = ZKZ' + \lambda I$ where $\lambda = \sigma_e^2 / \sigma_u^2$.
n.core	Setting n.core > 1 will enable parallel execution on a machine with multiple cores.
P3D	When P3D = TRUE, variance components are estimated by REML only once, without any markers in the model. When P3D = FALSE, variance components are estimated by REML for each marker separately.
optimizer	The function used in the optimization process. We offer "optim", "optimx", and "nlminb" functions.
eigen.G	A list with

\$values Eigen values

\$vectors Eigen vectors

The result of the eigen decomposition of $G = ZKZ'$. You can use "spectralG.cpp" function in RAINBOWR. If this argument is NULL, the eigen decomposition will be performed in this function. We recommend you assign the result of the eigen decomposition beforehand for time saving.

min.MAF Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.

count When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ for each marker

score.calc.score	<i>Calculate $-\log_{10}(p)$ of each SNP-set by the score test</i>
------------------	---

Description

This function calculates $-\log_{10}(p)$ of each SNP-set by the score test. First, the function calculates the score statistic without solving the multi-kernel mixed model for each SNP-set. Then it performs the score test by using the fact that the score statistic follows the chi-square distribution.

Usage

```
score.calc.score(
  M.now,
  y,
  X.now,
  ZETA.now,
  LL0,
  Gu,
  Ge,
  P0,
  map,
  kernel.method = "linear",
  kernel.h = "tuned",
```

```

haplotype = TRUE,
num.hap = NULL,
test.effect = "additive",
window.size.half = 5,
window.slide = 1,
chi0.mixture = 0.5,
weighting.center = TRUE,
weighting.other = NULL,
gene.set = NULL,
min.MAF = 0.02,
count = TRUE
)

```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA.now	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
LL0	The log-likelihood for the null model.
Gu	A $n \times n$ matrix. You should assign ZKZ' , where K is covariance (relationship) matrix and Z is its design matrix.
Ge	A $n \times n$ matrix. You should assign identity matrix I (diag(n)).
P0	$n \times n$ matrix. The Moore-Penrose generalized inverse of $SV0S$, where $S = X(X'X)^{-1}X'$ and $V0 = \sigma_u^2 Gu + \sigma_e^2 Ge$. σ_u^2 and σ_e^2 are estimators of the null model.
map	Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the forth column is $-\log_{10}(p)$ for each marker.
kernel.method	It determines how to calculate kernel. There are three methods. "gaussian" It is the default method. Gaussian kernel is calculated by distance matrix. "exponential" When this method is selected, exponential kernel is calculated by distance matrix. "linear" When this method is selected, linear kernel is calculated by NOIA methods for additive GRM.
kernel.h	The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.

num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.
test.effect	Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "aditive+dominance")
window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculated K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
window.slide	This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = $2 * \text{window.size.half} + 1$.
chi0.mixture	RAINBOWR assumes the test statistic $l1'Fl1$ is considered to follow a χ^2 distribution with $df = 0 + (1 - a) \times \text{chisq}(df = r)$, where $l1$ is the first derivative of the log-likelihood and F is the Fisher information. And r is the degree of freedom. The argument chi0.mixture is a $(0 \leq a < 1)$, and default is 0.5.
weighting.center	In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.
weighting.other	You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.
gene.set	If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ for each SNP-set

References

score.calc.score.MC *Calculate $-\log_{10}(p)$ of each SNP-set by the score test (multi-cores)*

Description

This function calculates $-\log_{10}(p)$ of each SNP-set by the score test. First, the function calculates the score statistic without solving the multi-kernel mixed model for each SNP-set. Then it performs the score test by using the fact that the score statistic follows the chi-square distribution.

Usage

```
score.calc.score.MC(
  M.now,
  y,
  X.now,
  ZETA.now,
  LL0,
  Gu,
  Ge,
  P0,
  n.core = 2,
  map,
  kernel.method = "linear",
  kernel.h = "tuned",
  haplotype = TRUE,
  num.hap = NULL,
  test.effect = "additive",
  window.size.half = 5,
  window.slide = 1,
  chi0.mixture = 0.5,
  weighting.center = TRUE,
  weighting.other = NULL,
  gene.set = NULL,
  min.MAF = 0.02,
  count = TRUE
)
```

Arguments

M.now	A n.sample x n.mark genotype matrix where n.sample is sample size and n.mark is the number of markers.
y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
X.now	A $n \times p$ matrix. You should assign mean vector (rep(1, n)) and covariates. NA is not allowed.
ZETA.now	A list of variance (relationship) matrix (K; $m \times m$) and its design matrix (Z; $n \times m$) of random effects. You can use only one kernel matrix. For example, ZETA = list(A = list(Z = Z, K = K)) Please set names of list "Z" and "K"!
LL0	The log-likelihood for the null model.
Gu	A $n \times n$ matrix. You should assign ZKZ' , where K is covariance (relationship) matrix and Z is its design matrix.

Ge	A $n \times n$ matrix. You should assign identity matrix I (diag(n)).
P0	A $n \times n$ matrix. The Moore-Penrose generalized inverse of $SV0S$, where $S = X(X'X)^{-1}X'$ and $V0 = \sigma_u^2Gu + \sigma_e^2Ge$. σ_u^2 and σ_e^2 are estimators of the null model.
n.core	Setting n.core > 1 will enable parallel execution on a machine with multiple cores.
map	Data frame of map information where the first column is the marker names, the second and third column is the chromosome and map position, and the fourth column is $-\log_{10}(p)$ for each marker.
kernel.method	It determines how to calculate kernel. There are three methods. "gaussian" It is the default method. Gaussian kernel is calculated by distance matrix. "exponential" When this method is selected, exponential kernel is calculated by distance matrix. "linear" When this method is selected, linear kernel is calculated by NOIA methods for additive GRM.
kernel.h	The hyper parameter for gaussian or exponential kernel. If kernel.h = "tuned", this hyper parameter is calculated as the median of off-diagonals of distance matrix of genotype data.
haplotype	If the number of lines of your data is large (maybe > 100), you should set haplotype = TRUE. When haplotype = TRUE, haplotype-based kernel will be used for calculating $-\log_{10}(p)$. (So the dimension of this gram matrix will be smaller.) The result won't be changed, but the time for the calculation will be shorter.
num.hap	When haplotype = TRUE, you can set the number of haplotypes which you expect. Then similar arrays are considered as the same haplotype, and then make kernel(K.SNP) whose dimension is num.hap x num.hap. When num.hap = NULL (default), num.hap will be set as the maximum number which reflects the difference between lines.
test.effect	Effect of each marker to test. You can choose "test.effect" from "additive", "dominance" and "additive+dominance". You also can choose more than one effect, for example, test.effect = c("additive", "additive+dominance")
window.size.half	This argument decides how many SNPs (around the SNP you want to test) are used to calculate K.SNP. More precisely, the number of SNPs will be $2 * \text{window.size.half} + 1$.
window.slide	This argument determines how often you test markers. If window.slide = 1, every marker will be tested. If you want to perform SNP set by bins, please set window.slide = $2 * \text{window.size.half} + 1$.
chi0.mixture	RAINBOWR assumes the test statistic $l1'F/l1$ is considered to follow a χ^2 distribution (df = 0) + (1 - a) χ^2 (df = r). where l1 is the first derivative of the log-likelihood and F is the Fisher information. And r is the degree of freedom. The argument chi0.mixture is a (0 <= a < 1), and default is 0.5.
weighting.center	In kernel-based GWAS, weights according to the Gaussian distribution (centered on the tested SNP) are taken into account when calculating the kernel if Rainbow = TRUE. If weighting.center = FALSE, weights are not taken into account.
weighting.other	You can set other weights in addition to weighting.center. The length of this argument should be equal to the number of SNPs. For example, you can assign SNP effects from the information of gene annotation.

gene.set	If you have information of gene, you can use it to perform kernel-based GWAS. You should assign your gene information to gene.set in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "geno" argument.
min.MAF	Specifies the minimum minor allele frequency (MAF). If a marker has a MAF less than min.MAF, it is assigned a zero score.
count	When count is TRUE, you can know how far RGWAS has ended with percent display.

Value

$-\log_{10}(p)$ for each SNP-set

References

Listgarten, J. et al. (2013) A powerful and efficient set test for genetic markers that handles confounders. *Bioinformatics*. 29(12): 1526-1533.

score.cpp	<i>Calculate $-\log_{10}(p)$ by score test (slow, for general cases)</i>
-----------	---

Description

Calculate $-\log_{10}(p)$ by score test (slow, for general cases)

Usage

```
score.cpp(y, Gs, Gu, Ge, P0, chi0.mixture = 0.5)
```

Arguments

y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
Gs	A list of kernel matrices you want to test. For example, Gs = list(A.part = K.A.part, D.part = K.D.part)
Gu	A $n \times n$ matrix. You should assign ZKZ' , where K is covariance (relationship) matrix and Z is its design matrix.
Ge	A $n \times n$ matrix. You should assign identity matrix I (diag(n)).
P0	A $n \times n$ matrix. The Moore-Penrose generalized inverse of $SV0S$, where $S = X(X'X)^{-1}X'$ and $V0 = \sigma_u^2Gu + \sigma_e^2Ge$. σ_u^2 and σ_e^2 are estimators of the null model.
chi0.mixture	RAINBOW assumes the test statistic $l1'F/l1$ is considered to follow a χ^2 distribution with $df = 0$ + $(1 - a) \times \chi^2$ with $df = r$, where $l1$ is the first derivative of the log-likelihood and F is the Fisher information. And r is the degree of freedom. The argument chi0.mixture is a $(0 \leq a < 1)$, and default is 0.5.

Value

$-\log_{10}(p)$ calculated by score test

score.linker.cpp	<i>Calculate $-\log_{10}(p)$ by score test (fast, for limited cases)</i>
------------------	---

Description

Calculate $-\log_{10}(p)$ by score test (fast, for limited cases)

Usage

```
score.linker.cpp(
  y,
  Ws,
  Gammas,
  gammas.diag = TRUE,
  Gu,
  Ge,
  P0,
  chi0.mixture = 0.5
)
```

Arguments

y	A $n \times 1$ vector. A vector of phenotypic values should be used. NA is allowed.
Ws	A list of low rank matrices (ZW; $n \times k$ matrix). This forms linear kernel $ZKZ' = ZW\Gamma(ZW)'$. For example, Ws = list(A.part = ZW.A, D.part = ZW.D)
Gammas	A list of matrices for weighting SNPs (Gamma; $k \times k$ matrix). This forms linear kernel $ZKZ' = ZW\Gamma(ZW)'$. For example, if there is no weighting, Gammas = lapply(Ws, function(x) diag(ncol(x)))
gammas.diag	If each Gamma is the diagonal matrix, please set this argument TRUE. The calculation time can be saved.
Gu	A $n \times n$ matrix. You should assign ZKZ' , where K is covariance (relationship) matrix and Z is its design matrix.
Ge	A $n \times n$ matrix. You should assign identity matrix I (diag(n)).
P0	A $n \times n$ matrix. The Moore-Penrose generalized inverse of $SV0S$, where $S = X(X'X)^{-1}X'$ and $V0 = \sigma_u^2Gu + \sigma_e^2Ge$. σ_u^2 and σ_e^2 are estimators of the null model.
chi0.mixture	RAINBOW assumes the statistic $l1'F/l1$ follows the mixture of χ_0^2 and χ_r^2 , where $l1$ is the first derivative of the log-likelihood and F is the Fisher information. And r is the degree of freedom. chi0.mixture determines the proportion of χ_0^2

Value

$-\log_{10}(p)$ calculated by score test

See

*Function to view the first part of data (like head(), tail())***Description**

Function to view the first part of data (like head(), tail())

Usage

```
See(
  data,
  fh = TRUE,
  fl = TRUE,
  rown = 6,
  coln = 6,
  rowst = 1,
  colst = 1,
  narray = 2,
  drop = FALSE,
  save.variable = FALSE,
  verbose = TRUE
)
```

Arguments

data	Your data. 'vector', 'matrix', 'array' (whose dimensions <= 4), 'data.frame' are supported format. If other formatted data is assigned, str(data) will be returned.
fh	From head. If this argument is TRUE, first part (row) of data will be shown (like head() function). If FALSE, last part (row) of your data will be shown (like tail() function).
fl	From left. If this argument is TRUE, first part (column) of data will be shown (like head() function). If FALSE, last part (column) of your data will be shown (like tail() function).
rown	The number of rows shown in console.
coln	The number of columns shown in console.
rowst	The start point for the direction of row.
colst	The start point for the direction of column.
narray	The number of dimensions other than row and column shown in console. This argument is effective only your data is array (whose dimensions >= 3).
drop	When rown = 1 or coln = 1, the dimension will be reduced if this argument is TRUE.
save.variable	If you want to assign the result to a variable, please set this argument TRUE.
verbose	If TRUE, print the first part of data.

Value

If save.variable is FALSE, NULL. If TRUE, the first part of your data will be returned.

spectralG.cpp

*Perform spectral decomposition (implemented by Rcpp)***Description**

Perform spectral decomposition for $G = ZKZ'$ or SGS where $S = I - X(X'X)^{-1}X$.

Usage

```
spectralG.cpp(
  ZETA,
  ZWs = NULL,
  X = NULL,
  weights = 1,
  return.G = TRUE,
  return.SGS = FALSE,
  spectral.method = NULL,
  tol = NULL,
  df.H = NULL
)
```

Arguments

ZETA	A list of variance (relationship) matrix (K ; $m \times m$) and its design matrix (Z ; $n \times m$) of random effects. You can use only one kernel matrix. For example, <code>ZETA = list(A = list(Z = Z, K = K))</code> Please set names of list "Z" and "K"!
ZWs	A list of additional linear kernels other than genomic relationship matrix (GRM). We utilize this argument in <code>RGWAS.multisnp</code> function, so you can ignore this.
X	$n \times p$ matrix. You should assign mean vector (<code>rep(1, n)</code>) and covariates. NA is not allowed.
weights	If the length of ZETA ≥ 2 , you should assign the ratio of variance components to this argument.
return.G	If this argument is TRUE, spectral decomposition results of G will be returned. ($G = ZKZ'$)
return.SGS	If this argument is TRUE, spectral decomposition results of SGS will be returned. ($S = I - X(X'X)^{-1}X$, $G = ZKZ'$)
spectral.method	The method of spectral decomposition. In this function, "eigen" : eigen decomposition and "cholesky" : cholesky and singular value decomposition are offered. If this argument is NULL, either method will be chosen according to the dimension of Z and X.
tol	The tolerance for detecting linear dependencies in the columns of $G = ZKZ'$. Eigen vectors whose eigen values are less than "tol" argument will be omitted from results. If tol is NULL, top 'n' eigen values will be effective.
df.H	The degree of freedom of K matrix. If this argument is NULL, <code>min(n, sum(nrow(K1), nrow(K2), ...))</code> will be assigned.

Value

- \$spectral.G** The spectral decomposition results of G.
- \$U** Eigen vectors of G.
- \$delta** Eigen values of G.
- \$spectral.SGS** Estimator for σ_e^2
- \$Q** Eigen vectors of SGS.
- \$theta** Eigen values of SGS.

SS_gwas	<i>Calculate some summary statistics of GWAS (genome-wide association studies) for simulation study</i>
---------	---

Description

Calculate some summary statistics of GWAS (genome-wide association studies) for simulation study

Usage

```
SS_gwas(  
  res,  
  x,  
  map.x,  
  qtn.candidate,  
  gene.set = NULL,  
  n.top.false.block = 10,  
  sig.level = c(0.05, 0.01),  
  method.thres = "BH",  
  inflator.plus = 2,  
  LD_length = 150000,  
  cor.thres = 0.35,  
  window.size = 0,  
  saveName = NULL,  
  plot.ROC = TRUE  
)
```

Arguments

- | | |
|---------------|---|
| res | Data frame of GWAS results where the first column is the marker names, the second and third column is the chromosome amd map position, and the forth column is -log10(p) for each marker. |
| x | A N (lines) x M (markers) marker genotype data (matrix), coded as -1, 0, 1 = aa, Aa, AA. |
| map.x | Data frame with the marker names in the first column. The second and third columns contain the chromosome and map position. |
| qtn.candidate | A vector of causal markers. You should assign where those causal markers are positioned in our marker genotype, rather than physical position of those causal markers. |

<code>gene.set</code>	If you have information of gene (or haplotype block), and if you used it to perform kernel-based GWAS, you should assign your gene information to <code>gene.set</code> in the form of a "data.frame" (whose dimension is (the number of gene) x 2). In the first column, you should assign the gene name. And in the second column, you should assign the names of each marker, which correspond to the marker names of "x" argument.
<code>n.top.false.block</code>	We will calculate the mean of $-\log_{10}(p)$ values of top 'n.top.false.block' blocks to evaluate the inflation level of results. The default is 10.
<code>sig.level</code>	Significance level for the threshold. The default is 0.05.
<code>method.thres</code>	Method for determining threshold of significance. "BH" and "Bonferroni" are offered.
<code>inflator.plus</code>	If 'the $-\log_{10}(p)$ value for each marker' exceeds ('the inflation level' + 'inflator.plus'), that marker is regarded as significant.
<code>LD_length</code>	SNPs within the extent of LD are regarded as one set. This <code>LD_length</code> determines the size of LD block, and $2 \times \text{LD_length}$ (b.p.) will be the size of LD block.
<code>cor.thres</code>	SNPs within the extent of LD are regarded as one set. This <code>cor.thres</code> also determines the size of LD block, and the region with square of correlation coefficients $\geq \text{cor.thres}$ is regarded as one LD block. More precisely, the regions which satisfies both <code>LD_length</code> and <code>cor.thres</code> condition is regarded as one LD block.
<code>window.size</code>	If you perform SNP-set analysis with sliding window, we can consider the effect of window size by this argument.
<code>saveName</code>	When drawing any plot, you can save plots in png format. In <code>saveName</code> , you should substitute the name you want to save. When <code>saveName = NULL</code> , the plot is not saved.
<code>plot.ROC</code>	If this argument is TRUE, ROC (Receiver Operating Characteristic) curve will be drawn with AUC (Area Under the Curve).

Value

\$log.p $-\log_{10}(p)$ values of the causals.

\$qtn.logp.order The rank of $-\log_{10}(p)$ of causals.

\$thres A vector which contains the information of threshold.

\$overthres The number of markers which exceed the threshold.

\$AUC Area under the curve.

\$AUC.relax Area under the curve calculated with LD block units.

\$FDR False discovery rate. $1 - \text{Precision}$.

\$FPR False positive rate.

\$FNR False negative rate. $1 - \text{Recall}$.

\$Recall The proportion of the number of causals detected by GWAS to the number of causals you set.

\$Precision The proportion of the number of causals detected by GWAS to the number of markers detected by GWAS.

\$Accuracy The accuracy of GWAS results.

\$Hm Harmonic mean of Recall and Precision.

\$haplo.name The haplotype block name which correspond to causals.

\$mean.false The mean of $-\log_{10}(p)$ values of top 'n.top.false.block' blocks.

\$max.trues Maximum of the $-\log_{10}(p)$ values of the region near causals.
